Overview

- The nature of the problem
- Background of existing methods
 - Pre-1995 methods
 - Recent methods
- Setting for our solution
- The intuition behind the algorithm
- Some details
- Some results
- Conclusion, limitations, and prospects

Why consider this problem?

- Sudden changes in lighting are common (If the geometry of the light sources are known in advance, existing incremental radiosity techniques can be used.)

How do *we* define dynamic?

- Scene geometry does not change
- Light sources (of arbitrary shape) can be added or removed

How do *we* define dynamic?

- Scene geometry does not change
- Light sources (of arbitrary shape) can be added or removed
- Straightforward solution
 - Introduce a new patch that models the light source, and recompute energy values
 - To turn of light source, shoot negative energy (keep the patch in memory, we may need it later on?)
 - Creation of patch and recomputing solution is time consuming.
- Our approach
 - Can we take a incremental solution for adding?
 - Can we modify the best solution out there?

Hierarchical Radiosity

- Trade complexity for error in a disciplined way
- Computation of geometric configuration (“formfactors”) is more time consuming than energy calculation
- Preprocess scenes by setting up energy exchange links.

Hierarchical Radiosity Interaction Computation

If we divide k patches into n elements, the total number of interactions is $O(n)$

```
Refine(Patch *p, Patch *q, float Feps, float Aeps) {  
    float Fpq, Fqp;  
    Fpq = FormFactEstimate(p,q); Fqp = FormFactEstimate(q,p);  
    if (Fpq < Fqp && Fqp < Feps) Link (p,q);  
    else {  
        if (Subdiv(q, Aeps)) {  
            Refine (p,q.nw,Feps,Aeps); Refine (p,q.ne,Feps,Aeps);  
            Refine (p,q.sw,Feps,Aeps); Refine (p,q.se,Feps,Aeps);  
        }  
        else  
            Link(p,q);  
    }  
}
```

Context of Prior Solution

Context of Prior Solution

- Introduce a **new** patch modeling light source (requires computation of the set of patches the user inputted light source may impact)
- Set up links again
- Implies throwing away some of the hardwork done

Intuition Behind Our Solution

- HR has subdivided the geometry
- What if nodes in our tree is a part of the unknown light source?
- **Straightforward to update patch properties of these nodes**

Intuition Behind Our Solution

- If the HR node is a proper subset of the light source ...
- Expand the node
- Recursively process the node

Adaptive Refinement: AR

- Mark the nodes that are *completely* inside the light source
- Sub divide nodes that partially intersects with the light source

Adaptive Refinement: AR

- Mark the nodes that are *completely* inside the light source
- Sub divide nodes that partially intersects with the light source
- Further refine node if it is a leaf in the hierarchical radiosity computation, and recurse
- Assign the emissivity of the light source to the *marked* nodes.

```
Algorithm Intersection(LightSource R, Quadtree Q)
  if Disjoint(R,Q) then
    return NULL;
  if Contained(R,Q) then /* Q is contained in R */
    return Q;
  else for each  $child_i$  of Q do
    Intersection (R,  $Q.child_i$ );
  }
```

Adaptive Refinement: AR

- Mark the nodes that are *completely* inside the light source
- Sub divide nodes that partially intersects with the light source
- Further refine node if it is a leaf in the hierarchical radiosity computation, and recurse
- Assign the emissivity of the light source to the *marked* nodes.
- Distribute the emissivity of a *marked* node to its descendents

```
Algorithm Intersection(LightSource R, Quadtree Q)
  if Disjoint(R,Q) then
    return NULL;
  if Contained(R,Q) then /* Q is contained in R */
    return Q;
  else for each  $child_i$  of Q do
    Intersection (R,  $Q.child_i$ );
  }
```

What if there is too much adaptive refinement?

AR may take considerable time when:

- Scenes are dense
- User introduced light source is not axis aligned with patch boundaries

What if there is too much adaptive refinement?

AR may take considerable time when:

- Scenes are dense
- User introduced light source is not axis aligned with patch boundaries
- A faster solution (Fractional Emissivity(FE))
 - Do not refine the node if it is a HR leaf

What if there is too much adaptive refinement?

AR may take considerable time when:

- Scenes are dense
- User introduced light source is not axis aligned with patch boundaries
- A faster solution (Fractional Emissivity(FE))
 - Do not refine the node if it is a HR leaf
 - Calculate the fractional overlap (Δf) with the light source
 - $E_{node} = \Delta f * E_{lightSource}$
 - Requires a clipping algorithm such as Sutherland-Hodgman
- Disadvantages of FE: Coarser approximation of light source
