Automated Reasoning 2020

Lecture 22: Maxsat - an application of SAT oracle

Instructor: Ashutosh Gupta

IITB, India

Compile date: 2020-11-13

Oracle

In computer science, oracle is an algorithm that can solve a hard problem.

Often complexity or security arguments depend on the availability or absence of such oracles.

SAT solver is the quintessential oracle used for many harder problems, e.g., maxsat.

Topic 22.1

Maxsat

Maxsat

Input:

- ► A CNF fromula *F*
- ▶ A weight function $w: F \to \mathbb{N}$
 - maps each clause in F to a number

Output:

Find a model m such that the following sum is maximum.

$$\sum_{C \in F} w(C) m(C)$$

Commentary: m(C) is 1 if $m \models C$, otherwise 0.

Partial maxsat

Input:

- ► A CNF fromula *Hard* ∧ *Soft*
- ▶ A weight function $w : Soft \rightarrow \mathbb{N}$

Output:

There may be no solutions.

Find a model m such that m
vert Hard and the following sum is maximum.

$$\sum_{C \in Soft} w(C)m(C)$$

Many interesting optimization problems can be encoded into maxsat problem.

Example: shortest path on a graph

Example 22.1

Consider an undirected graph (V, E). Find shortest path between two nodes $s, g \in V$

- \triangleright We choose a Boolean variable p_v for each vertex v, indicating if v is visited.
- Hard constraints

$$p_s \wedge p_g$$

$$p_s \Rightarrow \sum_{v' \in E(s)} p_{v'} = 1$$

$$\begin{array}{c}
v \in V - \{s, g\} & v' \in E(v) \\
p_g \Rightarrow \sum_{v' \in E(g)} = 1
\end{array}$$

(source has exactly one successor)

(one neighbour to enter and the other to leave)

(goal has exactly one predecessor)

(source and goal must be visited)

▶ Soft constraints $\bigwedge_{v \in V} \neg p_v$

Topic 22.2

Methods for maxsat

Methods for maxsat

There has been many proposed methods.

- ► Branch-and-bound
- ► Integer arithmetic solver based (IP)
- SAT solvers based algorithms
- ► Implicit hitting set algorithms (IP/Hybrid)

We will focus on only one class of them.

For further details: https://www.cs.helsinki.fi/group/coreo/aaai16-tutorial/aaai16-maxsat-tutorial.pdf

Unweighted Partial maxsat

In this lecture, we will only discuss the unweighted maxsat problem

Input:

► A CNF fromula *Hard* ∧ *Soft*

Output:

Find a model m such that $m \models Hard$ and the following sum is maximum.

$$\sum_{C \in Soft} m(C)$$

How a SAT solver methods works?

By setup initially, $\not\models Soft \land Hard$. Iteratively, relax Soft constraints until $\models Soft \land Hard$.

- 1. If $\not\models Hard$, return no maxsat solution
- 2. If $m \models Soft \wedge Hard$, return found optimal m
- 3. Relax Soft so that more clauses allowed to be false in the original Soft
- 4. go to 2.

We will cover a few instances of the above design

- Iterative linear search
- Core based search

Blocking variables to allow false soft clauses

maxsat methods often use blocking variables to relax (block) soft clauses.

▶ In a soft clause $x_1 \vee \vee x_k$ we insert a new variable b

$$b \vee x_1 \vee ... \vee x_k$$

b is fresh with respect to the formula.

- ▶ If b = 0 the soft clause has to be satisfied.
- \triangleright If b=1 the extended clause is already satisfied and the soft clause is blocked, i.e., no requirement to satisfy the soft clause.

Example 22.2

@(1)(\$)(3)

Recall the shortest path soft clauses $\bigwedge_{v \in V} \neg p_v$

Consider a clause $\neg p_x$ for some node $x \in V$.

Corresponding clause with blocking variable $(\neg p_x \lor b_x)$ Automated Reasoning 2020

Iterative linear search

- 1. Insert a blocking variable b_c in every $c \in Soft$.
- 2. k := 0
- 3. If $\models Hard \land Soft \land CNF(\sum b_c \leq k)$, return k
- 4. k := k + 1.
- 5. goto 3.

at most k soft clauses can be blocked

Exercise 22.1

Can we improve on the search of k?

Iterative linear search in the other direction

$\mathsf{SAT} \to \mathsf{UNSAT}$

- 1. Insert a blocking variable b_c in every $c \in Soft$.
- 2. Get m such that $m \models Hard$
- 3. k := #(of voilated clauses in Soft by m)-1
- 4. If there is a better $m \models Hard \land Soft \land CNF(\sum b_c \le k)$, goto 3
- 5. return k.

after every iteration *m* violates fewer clauses in *Soft*

Exercise 22.2

Can we improve on the search of k like the previous algorithm?

Core based maxsat solving

In the last algorithm, we could guide our search using the model.

In case of unsatisfiability there is no guidance.

Definition 22.1

An unsat core of an maxsat problem Hard \land Soft is a subset $F \subseteq S$ oft such that Hard \land F is unsatisfiable.

We usually expect F to be significantly smaller than Soft.

Modern solvers can return an unsat cores in the case of unsatisfiability.

Iterative linear search with unsat core

- 1. $k := 0, BV = \{\}$
- 2. If $\models Hard \land Soft \land CNF(\sum_{b_c \in BV} b_c \leq k)$, return k
- 3. Otherwise, get unsat core K of $Hard \wedge Soft \wedge CNF(\sum_{b_c \in BV} b_c \leq k)$
- 4. For each $c \in K$ that has no blocking variable.
 - 4.1 Insert a blocking variable b_c in c and $BV = BV \cup \{b_c\}$.
- 5. k := k + 1.
- 6. goto 2.

The clauses that have participated in cores have blocking variables.

Now cardinality constraints are over far fewer variables.

Therefore, tighter relaxation and less waste full search in satisfiability checks.

Exercise 22.3

- a. Show that this algorithm obtains the maximum?
- b. How can we incrementally construct cardinality constraints?

Example: core restricted cardinality constraints

Example 22.3

Recall the shortest path soft clauses $\bigwedge_{v \in V} \neg p_v$

Let us suppose we got two unsat cores $\{\neg p_x, \neg p_y\}$ and $\{\neg p_u, \neg p_v, \neg p_w\}$ in first two iterations.

In previous algorithm, we will insert blocking bits b_x , b_y , b_y , b_y , b_w as follows

- $ightharpoonup \neg p_{\times} \vee b_{\times}$
- $ightharpoonup \neg p_y \lor b_y$
- $ightharpoonup \neg p_u \lor b_u$
- $ightharpoonup \neg p_{v} \lor b_{v}$
- $ightharpoonup \neg p_{w} \lor b_{w}$

We will add cardinality constraint $b_x + b_y + b_u + b_v + b_w \le 2$.

We are still relaxing too much?

We are adding

$$b_x + b_y + b_u + b_v + b_w \le 2$$

We are asking the solver to block at most any two of the five soft constraints.

It may end up blocking $\neg p_x$ and $\neg p_y$.

We already know that there is no solution for this blocking combination, since nothing is blocked from the other unsat core.

We can be more precise and add $b_x + b_y \le 1 \land b_u + b_v + b_w \le 1$

Exactly one soft clause is to be blocked from each core.

Overlapping cores

If cores overlap we can not add separate learned inequalities?

Example 22.4

Let us suppose we got two unsat cores $\{\neg p_x, \neg p_y\}$ and $\{\neg p_x, \neg p_v, \neg p_w\}$ in first two iterations.

We cannot add two constraints $b_x + b_y \le 1 \land b_x + b_y + b_w \le 1$.

Since $b_x = 1$ and $b_y = 1$ removes both cores and is not satisfied by the above constraints.

If overlap we have to create inequalities that is combined.

Two solutions

- ► Fresh blocking variable for each core (Fu-malik)
- ▶ Maintain disjoint sets of clauses of overlapping cores

Fu-Malik: fresh blocking variable for each core

- 1. k := 0,
- 2. If $\models Hard \land Soft$, return k
- 3. Otherwise, get unsat core K of $Hard \wedge Soft$
- 4. $BV = \{\}$
- 5. For each $c \in K$.
 - 5.1 Insert a fresh blocking variable b_c in c and $BV = BV \cup \{b_c\}$.
- 6. Hard := Hard \land CNF $(\sum_{b_c \in BV} b_c \le 1)$
- 7. k := k + 1.
- 8. goto 2.

A clause may get multiple blocking variable.

Since we compare with 1 only, simpler constraints!!

Overlapping cores

Example 22.5

Let us again consider two unsat cores $\{\neg p_x, \neg p_v\}$ and $\{\neg p_x, \neg p_v, \neg p_w\}$ in first two iterations.

A blocking bit for each clause in each core.

- $ightharpoonup \neg p_x \lor b_{x1} \lor b_{x2}$
- $ightharpoonup \neg p_{v} \lor b_{v}$
- $ightharpoonup \neg p_{ii} \lor b_{ii}$
- $ightharpoonup \neg p_{V} \lor b_{V}$
- $ightharpoonup \neg p_{w} \vee b_{w}$

Gets two blocking variables, since $\neg p_x$ occurs in two cores.

Adds too many new variables with symmetric roles. Burden on future iterations.

Maintain disjoint core covers

We can keep that records of cores that do not overlap.

Definition 22.2

A cover is a set of overlapping cores and two covers do not have cores that overlap with each other.

We maintain a set Covers of covers.

▶ Let $F[Covers] := \bigwedge_{Cover \in Covers} CNF(\sum_{b_c \in K \in Cover} b_c \le |Cover|)$.

Number of cores in the cover

Instructor: Ashutosh Gupta

- ightharpoonup Let Covers' := mergeCover(Covers, K) insert core K in Covers as follows
 - 1. $Covers' = \{\}$, $NewCover = \{K\}$
 - 2. For each Cover ∈ Covers
 - ▶ If $\exists K' \in Cover. \ K' \cap K \neq \emptyset$, $NewCover := NewCover \cup Cover$
 - ▶ Otherwise, $Covers' := Covers' \cup \{Cover\}$
 - 3. return Covers' ∪ {NewCover}

Example: cover

Example 22.6

Consider unsat cores after five iterations.

Covers := {
$$\left\{ \begin{array}{ccc} \{\neg p_x, \neg p_y\}, & \{\neg p_x, \neg p_z\} \\ \{ \neg p_u, \neg p_v\}, & \{\neg p_a, \neg p_w\}, & \{\neg p_a, \neg p_v, \neg p_c\} \end{array} \right\}$$

$$F[Covers] := b_x + b_y + b_z < 2 \land b_u + b_v + b_w + b_a + b_c < 3$$

Maxsat via core covers

- 1. k := 0, $Covers = \{\}$
- 2. If \models *Hard* \land *Soft* $\land \land F[Covers]$, return k
- 3. Otherwise, get unsat core K of $Hard \wedge Soft \wedge F[Covers]$
- 4. Covers := mergeCovers(Covers, K).
- 5. k := k + 1.
- 6. goto 2.
