Lecture 9: Common Mathematical  
Functions

# About These Slides

- Based on Chapter 8 of the book *An Introduction to Programming Through C++* by Abhiram Ranade (Tata McGraw Hill, 2014)
- Original slides by Abhiram Ranade
  - First update by Varsha Apte
  - Second update by Uday Khedker

# Learn Methods For Common Mathematical Operations

- Evaluating common mathematical functions such as  
Sin(x)  
log(x)
- Integrating functions numerically, i.e. when you do not know the closed form
- Finding roots of functions, i.e. determining where the function becomes 0
- All the methods we study are approximate. However, we can use them to get answers that have as small error as we want
- The programs will be simple, using just a single loop

# Outline

- McLaurin Series (to calculate function values)
- Numerical Integration
- Bisection Method
- Newton-Raphson Method

# MacLaurin Series

When  $x$  is close to 0:

$$f(x) = f(0) + f'(0)x + \frac{f''(0)x^2}{2!} + \frac{f'''(0)x^3}{3!} + \dots$$

E.g. if  $f(x) = \sin x$

$$f(x) = \sin(x), \quad f(0) = 0$$

$$f'(x) = \cos(x), \quad f'(0) = 1$$

$$f''(x) = -\sin(x), \quad f''(0) = 0$$

$$f'''(x) = -\cos(x), \quad f'''(0) = -1$$

$$f''''(x) = \sin(x), \quad f''''(0) = 0$$

Now the pattern will repeat

# Example

Thus  $\sin(x) = x - x^3/3! + x^5/5! - x^7/7! \dots$

A fairly accurate value of  $\sin(x)$  can be obtained by using sufficiently many terms

Error after taking  $i$  terms is at most the absolute value of the  $i+1$ th term

# Program Plan-High Level

$$\sin(x) = x - x^3/3! + x^5/5! - x^7/7! \dots$$

Use the *accumulation idiom*

Use a variable called **term**

This will keep taking successive values of the terms

Use a variable called **sum**

Keep adding **term** into this variable

# Program Plan: Details

$$\sin(x) = x - x^3/3! + x^5/5! - x^7/7! \dots$$

- Sum can be initialized to the value of the first term So  
sum = x
- Now we need to figure out initialization of term and it's  
update
- First figure out how to get the  $k$ th term from the  $(k-1)$  th  
term

# Program Plan: Terms

$$\sin(x) = x - x^3/3! + x^5/5! - x^7/7! \dots$$

Let  $t_k$  = kth term of the series,  $k=1, 2, 3\dots$

$$t_k = (-1)^{k+1} x^{2k-1} / (2k-1)!$$

$$t_{k-1} = (-1)^k x^{2k-3} / (2k-3)!$$

$$t_k = (-1)^k x^{2k-3} / (2k-3)! * (-1)(x^2) / ((2k-2)(2k-1))$$

$$= - t_{k-1} (x)^2 / ((2k-2)(2k-1))$$

# Program Plan

- Loop control variable will be  $k$
- In each iteration we calculate  $t_k$  from  $t_{k-1}$
- The term  $t_k$  is added to **sum**
- A variable **term** will keep track of  $t_k$   
At the beginning of  $k^{\text{th}}$  iteration, **term** will have the value  $t_{k-1}$ , and at the end of  $k^{\text{th}}$  iteration it will have the value  $t_k$
- After  $k^{\text{th}}$  iteration, **sum** will have the value = sum of the first  $k$  terms of the Taylor series
- Initialize **sum = x**, **term = x**
- In the first iteration of the loop we calculate the sum of 2 terms. So initialize **k = 2**
- We stop the loop when **term** becomes small enough

# Program

```
main_program{  
    double x; cin >> x;  
    double epsilon = 1.0E-20; // arbitrary.  
    double sum = x, term = x;  
    for(int k=2; abs(term) > epsilon; k++){  
        term *= -x*x / (2*k - 1) / (2*k - 2);  
        sum += term;  
    }  
    cout << sum << endl;  
}
```

# Numerical Integration (General)

Integral from  $p$  to  $q$  = area under curve

Approximate area by rectangles

# Plan (General)

- Read in  $p, q$  (assume  $p < q$ )
- Read in  $n =$  number of rectangles
- Calculate  $w =$  width of rectangle  $= (q-p)/n$
- $i$ th rectangle,  $i=0, 1, \dots, n-1$  begins at  $p+iw$
- Height of  $i$ th rectangle  $= f(p+iw)$
- Given the code for  $f$ , we can calculate height and width of each rectangle and so we can add up the areas

# Example: Numerical Integration To Calculate $\ln(x)$

$\ln(x)$  = natural logarithm

=  $\int 1/x \, dx$  from 1 to  $x$

= area under the curve  $f(x)=1/x$  from 1 to  $x$

```
double x; cin >> x;
double n; cin >> n;
double w = (x-1)/n; // width of each rectangle
double area = 0;
for(int i=0; i<n; i++)
    area = area + w * 1/(1+i*w);
cout << area << endl;
```

# Remarks

- By increasing  $n$ , we can get our rectangles closer to the actual function, and thus reduce the error
- However, if we use too many rectangles, then there is roundoff error in every area calculation which will get added up
- We can reduce the error also by using trapeziums instead of rectangles, or by setting rectangle height = function value at the midpoint of its width  
Instead of  $f(p+iw)$ , use  $f(p+iw + w/2)$
- For calculation of  $\ln(x)$ , you can check your calculation by calling built-in function  $\log(x)$

# Bisection Method For Finding Roots

- Root of function  $f$ : Value  $x$  such that  $f(x)=0$
- Many problems can be expressed as finding roots, e.g. square root of  $w$  is the same as root of  $f(x) = x^2 - w$
- Requirement:
  - Need to be able to evaluate  $f$
  - $f$  must be continuous
  - We must be given points  $x_L$  and  $x_R$  such that  $f(x_L)$  and  $f(x_R)$  are not both positive or both negative

# Bisection Method For Finding Roots

- Because of continuity, there must be a root between  $x_L$  and  $x_R$  (both inclusive)
- Let  $x_M = (x_L + x_R)/2 =$  midpoint of interval  $(x_L, x_R)$
- If  $f(x_M)$  has same sign as  $f(x_L)$ , then  $f(x_M)$ ,  $f(x_R)$  have different signs  
So we can set  $x_L = x_M$  and repeat
- Similarly if  $f(x_M)$  has same sign as  $f(x_R)$
- In each iteration,  $x_L$ ,  $x_R$  are coming closer.
- When they come closer than certain epsilon, we can declare  $x_L$  as the root

# Bisection Method For Finding Square Root of 2

- Same as finding the root of  $x^2 - 2 = 0$
- Need to support both scenarios:
  - $x_L$  is negative,  $x_R$  is positive
  - $x_L$  is positive,  $x_R$  is negative
- We have to check if  $x_M$  has the same sign as  $x_L$  or  $x_R$

# Bisection Method for Finding $\sqrt{2}$

```
double xL=0, xR=2, xM, epsilon=1.0E-20;
```

```
// Invariant:  $xL < xR$ 
```

```
while(xR - xL >= epsilon){ // Interval is still large
    xM = (xL+xR)/2; // Find the middle point
    bool xMisNeg = (xM*xM - 2) < 0;
    if(xMisNeg) // xM is on the side of xL
        xL = xM;
    else xR = xM; // xM is on the side of xR
    // Invariants continues to remain true
}
cout << xL << endl;
```

# Newton Raphson method

- Method to find the root of  $f(x)$ , i.e.  $x$  s.t.  $f(x)=0$
- Method works if:
  - $f(x)$  and derivative  $f'(x)$  can be easily calculated
  - A good initial guess  $x_0$  for the root is available
- Example: To find square root of  $y$ 
  - use  $f(x) = x^2 - y$ .  $f'(x) = 2x$
  - $f(x)$ ,  $f'(x)$  can be calculated easily. 2,3 arithmetic ops
- Initial guess  $x_0 = 1$  is good enough!

# How To Get Better $x_{i+1}$ Given $x_i$

Point A =  $(x_i, 0)$  known

Calculate  $f(x_i)$

Point B =  $(x_i, f(x_i))$

Draw the tangent to  $f(x)$

C = intercept on x axis

C =  $(x_{i+1}, 0)$

$f'(x_i)$  = derivative  
=  $(d f(x))/dx$  at  $x_i$   
 $\approx AB/AC$

$$x_{i+1} = x_i - AC = x_i - AB / (AB/AC) = x_i - f(x_i) / f'(x_i)$$

# Square root of $y$

$$x_{i+1} = x_i - f(x_i) / f'(x_i)$$

$$f(x) = x^2 - y, \quad f'(x) = 2x$$

$$x_{i+1} = x_i - (x_i^2 - y)/(2x_i) = (x_i + y/x_i)/2$$

Starting with  $x_0=1$ , we compute  $x_1$ , then  $x_2$ , ...

We can get as close to  $\text{sqrt}(y)$  as required

Proof not part of the course.

# Computing $\sqrt{y}$ Using the Newton Raphson Method

```
float y; cin >> y;

float xi=1; // Initial guess. Known to work

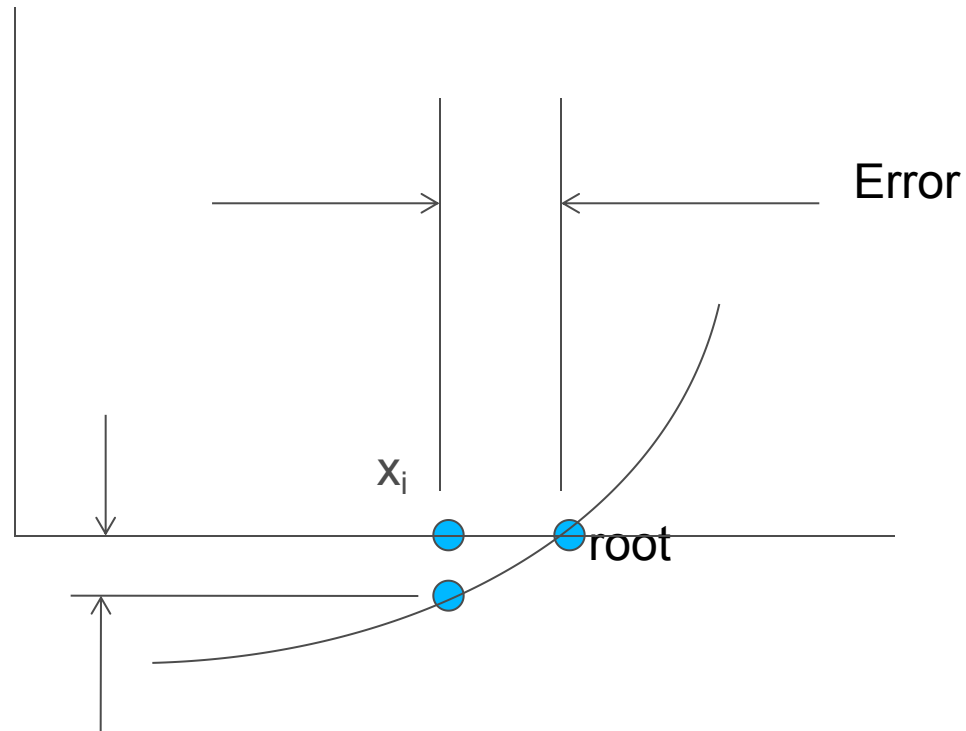

repeat(10){ // Repeating a fixed number of times

    xi = (xi + y/xi)/2;

}

cout << xi;
```

# How To Iterate Until Error Is Small

$$\text{Error Estimate} = |f(x_i)| = |x_i^* x_i - y|$$

# Make $|x_i * x_i - y|$ Small

```
float y; cin >> y;

float xi=1;

while(abs(xi*xi - y) > 0.001){

    xi = (xi + y/xi)/2 ;

}

cout << xi;
```

# Concluding Remarks

If you want to find  $f(x)$ , then

use MacLaurin series for  $f$ , if  $f$  and its derivatives can be evaluated at 0

Express  $f$  as an integral of some easily evaluable function  $g$ , and use numerical integration

Express  $f$  as the root of some easily evaluable function  $g$ , and use bisection or Newton-Raphson

All the methods are iterative, i.e. the accuracy of the answer improves with each iteration
