## Plan for Lecture 18

- Normalization Strategies
- Prolog code
- Java code

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 2 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Indexing Positions/Subterms

- A position  $\lambda$  identifies a subterm
- In above example  $t/2.2 = s(0) * 0$
- Notation for replacing a subterm  $t'$  in a term  $t$  by another term  $u$

$$t[\lambda \leftarrow u]$$

- Example:

$$t[2 \leftarrow 0] = (s(0) * s(0)) + 0$$

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 3 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Redex

Let  $t$  be a term and  $R$  a set of rewrite rules.

A redex in  $t$  is a position  $\lambda$  in  $t$  where some rule of  $R$  can apply. That is,  $\lambda$  is a redex in  $t$  if there is a rule  $l \rightarrow r$  in  $R$  and a substitution  $\sigma$  such that  $l\sigma == t/\lambda$ .

has 3 redexes— 1, 2 and 2.2

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 4 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Outermost and Innermost

A redex  $r$  in  $t$  is **outermost** if no **prefix** of  $r$  is also a redex. (Informally: no superterm can be reduced)

A redex  $r$  in  $t$  is **innermost** if there is no position  $r1$  in  $t$  with  $r$  as **prefix** such that  $r1$  is also a redex. (Informally: no subterm can be reduced)

In

2 is an outermost redex.

2.2 is an innermost redex.

1 is both innermost and outermost redex.

# Rewriting Strategy

Let  $t$  be a term and  $R$  a set of rules.

A reduction sequence

$$t \rightarrow t_1 \rightarrow t_2 \rightarrow \dots$$

is outermost (innermost) if each at step in the sequence a rule is applied at an outermost (innermost) redex.

A **mixed** strategy is one which is neither outermost nor innermost.

Which strategy is best?

Implement all 3 strategies.

# Term Rewriting in Java

Prolog code easier to understand?

- Separate Classes for
  - Term
  - Subst
  - Rule
- With appropriate methods

A term is an object which has methods to do things such as

- convert itself to string (for printing)
- applying a substitution on itself
- checking equality with another term
- matching with another term
- normalizing itself using some rules

# Vectors versus Arrays

Arrays are **fixed** size.

Not good when we do not know **arity** (number of arguments of a term) or we wish to input unknown number of rules etc.

Vectors are good for this.

Java has built-in Vector class which can hold a dynamic list of objects. Useful methods.

- `Vector rules = new Vector();`
- `rules.addElement(anyObject);`
- `rules.elementAt(i);` //starts from 0
- `int nrules = rules.size();`

# Type Casting

A vector is a list of Objects. So, when adding to a vector we can add **anything**.

When retrieving elements from a Vector we have to **typecast** it properly. Example- let arguments of a term be stored in a vector. Then,

```
for (int i = 0;
      i < t.args.size(); i++){
    Term targ = (Term) t.args.elementAt(i);
    << do something with targ >>
}
```

[Home Page](#)[Title Page](#)[Contents](#)[<<](#)[>>](#)[<](#)[>](#)[Page 9 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Term.java

```
public class Term {
// the 2 important fields of any term
public String opvarname;
public Vector args;
// The Term constructor below builds
// from a String such as "f(x,0,g(y,z))"
public Term(String str){
    ... }
//methods
public boolean isvar()
public boolean isconst()
// compare with another term.
public boolean equals(Term t)
// replace one of the top level arguments in term
// to make a new term. e.g.  f(a,b).rplarg(1,b) gives f(b,b)
public Term rplarg(int j, Term narg)
// make a new copy with varnames suffixed by a number.
public Term copy(int vnum)
// apply a substitution to a term
public Term applySubst(Subst sigma)
... And many more ...
}
```

# Parsing a term from a String

No error checking below.

```
public Term(String str){
    args = new Vector(); // initialize to null Vector.
    int i1 = str.indexOf('(');
    if (i1 == -1){
        // this is a constant or a variable
        opvarname = str;
    }
    else {
        // this is f(t1,...,tn) where n is arity of f
        opvarname = str.substring(0, i1);
        int paren = 1;
        while (paren > 0) {
            for (int pos = i1 + 1; pos <= str.length(); pos++){
                char ch = str.charAt(pos);
                if (ch == '(')
                    paren++;
                else if (ch == ')'){
                    paren--;
                    if (paren == 0){
                        args.addElement(new Term(str.substring(i1 + 1, pos)));
                        i1 = pos;
                        break;}
                }
                else if (str.charAt(pos) == ','){
                    if (paren == 1){
                        args.addElement(new Term(str.substring(i1 + 1, pos)));
                        i1 = pos;
                        break;}
                }
            }
        }
    }
}
```

```
// replace one of the top level arguments in term
// to make a new term. e.g. f(a,b).rplarg(1,b) gives f(b,b)
// no error checking done for now.
public Term rplarg(int j, Term narg){
    String tmp = this.opvarname + "(";
    for (int i = 0; i < args.size(); i++){
        if (i == j) {tmp = tmp + narg + ",";}
        else{ Term targ = (Term) args.elementAt(i);
            tmp = tmp + targ + ",";}}
    //remove extra , at end and add )
    return new Term(tmp.substring(0,tmp.length()-1) + ")")
```

# Representing Substitutions

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 12 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

A Vector of bindings!

```
// need binding <var, term> class first
```

```
class Bind{
    public String var;
    public Term  term;
    Bind(String v, Term t){
        var = v; term = t;} }
```

```
// a substitution is a Vector of bindings
```

```
// with various methods for adding binding, composing etc.
```

```
// how to represent failed subst?
```

```
// we use a boolean field isValid
```

```
public class Subst{
    public boolean isValid = false;
    public Vector sigma;
    // initialize to ID substitution
    Subst(){
        sigma = new Vector();
        isValid = true;
    }
```

# Substitution Methods

```
public Subst appendBind(String v, Term t){  
    // no checking here. simply add at end. ok for matching  
    // and when we have normalized already  
    sigma.addElement(new Bind(v,t));  
    return this;  
}
```

```
public boolean isBound(String var)
```

```
public Term getBind(String v)  
public String toString()
```

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 13 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Method for matching

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 14 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

```
public Subst match(Term t){  
    // returns a sigma such that t matches this term.  
    Subst idSub = new Subst();  
    return this.match1(t,idSub);}
```

```
public Subst match1(Term t, Subst sigma){  
    // assumed that t shares no variable with this term.  
    if (t.isvar()){  
        return sigma.appendBind(t.opvarname, this);}  
    else if (t.opvarname.equals(this.opvarname)){  
        for (int i = 0; i < t.args.size(); i++){  
            Term targ = (Term) t.args.elementAt(i);  
            Term sarg = (Term) this.args.elementAt(i);  
            sigma = sarg.match1(targ.applySubst(sigma), sigma);  
            if (! sigma.isValid){break;}}}  
    else{sigma.isValid=false;};  
    return sigma;}
```

Unification code similar, but more complex.

Must **compose** substs instead of appending!

# Representing Rules

```
public class Rule{
    // a rule has lhs and rhs
    public Term lhs;
    public Term rhs;
    // may wish to add other fields like rulenum later

    // a constructor for parsing a string and making a rule
    Rule(String str){
        // assumed to have l -> r with -> as separator

        // a method to change names of vars in a rule
        public Rule copy(int num){

            // read a set of rules from a file. A static method.
            public static Vector readRules(String fname)

            // print rules on terminal
            public static void writeRules(Vector Rules){
```

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 15 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Applying a rule

```
// a method that tries to use this rule on input term once.
public Term rwany(Term t){
    // this rewrites the term ONCE if possible anywhere using
    // return t itself if no rewriting is possible anywhere.
    Subst sig = t.match(lhs);
    if (sig.isValid){
        Term t1 = rhs.applySubst(sig);
        System.out.println(" Rule: " + this +
                           " rewrites " + t + " --> " + t1);

        return t1;}
    else if (t.isvar() | t.isconst())
        return t;
    else{
        for (int i = 0; i < t.args.size(); i++){
            Term targ = (Term) t.args.elementAt(i);
            Term t1 = this.rwany(targ);
            if (!(t1.equals(targ)))
                {return t.rplarg(i,t1);}};
        return t;}}
```

[Home Page](#)[Title Page](#)[Contents](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 16 of 18](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

# Computing Normal form

A method on a term.

```
// normalize the term using a set of rules.
public Term norm(Vector rules){
    for (int i = 0; i < rules.size(); i++){
        Rule rule = (Rule) rules.elementAt(i);
        Term ans = rule.rwany(this);
        if (! ans.equals(this)){
            return ans.norm(rules);}}};
return this; // if no rule applies at all
}
```

# Putting it all together

Main.java

```
import java.io.*;
import java.util.*;

public class Main {
    public static void main(String[] agmts){
        Vector rules = Rule.readRules(agmts[0]);
        Rule.writeRules(rules);
        Term t1,t2;
        // t1 = new Term("*(s(0),+(s(0),s(0)))");
        t1 = Term.getTerm();
        t2 = t1.norm(rules);
        System.out.println(t2 + " is normal form of " + t1);
    }
}
```
