

Introduction to Machine Learning - CS725  
Instructor: Prof. Ganesh Ramakrishnan  
Lecture 9 - Optimization Foundations Applied to  
Regression Formulations

# Building on questions on Least Squares Linear Regression

- 1 Is there a probabilistic interpretation?
  - Gaussian Error, Maximum Likelihood Estimate
- 2 Addressing overfitting
  - Bayesian and Maximum A posteriori Estimates, Regularization, Support Vector Regression
- 3 How to minimize the resultant and more complex error functions?
  - Level Curves and Surfaces, Gradient Vector, Directional Derivative, Gradient Descent Algorithm, Convexity, Necessary and Sufficient Conditions for Optimality

- 1-norm Error, and  $L_2$  regularized:

- $$\min_{\mathbf{w}, b, \xi_i, \xi_i^*} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_i (\xi_i + \xi_i^*)$$

s.t.  $\forall i,$   
 $y_i - \mathbf{w}^\top \phi(\mathbf{x}_i) - b \leq \epsilon + \xi_i,$   
 $b + \mathbf{w}^\top \phi(\mathbf{x}_i) - y_i \leq \epsilon + \xi_i^*,$   
 $\xi_i, \xi_i^* \geq 0$

- 2-norm Error, and  $L_2$  regularized:

- $$\min_{\mathbf{w}, b, \xi_i, \xi_i^*} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_i (\xi_i^2 + \xi_i^{*2})$$

s.t.  $\forall i,$   
 $y_i - \mathbf{w}^\top \phi(\mathbf{x}_i) - b \leq \epsilon + \xi_i,$   
 $b + \mathbf{w}^\top \phi(\mathbf{x}_i) - y_i \leq \epsilon + \xi_i^*$

- Here, the constraints  $\xi_i, \xi_i^* \geq 0$  are not necessary

# Need for Optimization so far

- **Unconstrained (Penalized) Optimization:**

$$\mathbf{w}_{Reg} = \arg \min_{\mathbf{w}} \|\Phi \mathbf{w} - \mathbf{y}\|_2^2 + \Omega(\mathbf{w})$$

- **Constrained Optimization 1:**

$$\mathbf{w}_{Reg} = \arg \min_{\mathbf{w}} \|\Phi \mathbf{w} - \mathbf{y}\|_2^2$$

*such that*  $\Omega(\mathbf{w}) \leq \theta$

- **Constrained Optimization 2 ( $t = 1$  or  $2$ ):**

$$\arg \min_{\mathbf{w}, b, \xi_i, \xi_i^*} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_i (\xi_i^t + \xi_i^{*t})$$

s.t.  $\forall i, y_i - \mathbf{w}^\top \phi(\mathbf{x}_i) - b \leq \epsilon + \xi_i$ ;  $b + \mathbf{w}^\top \phi(\mathbf{x}_i) - y_i \leq \epsilon + \xi_i^*$

- **Equivalence:**  $\lambda$  (Penalized)  $\equiv \theta$  (Constrained)
- **Duality:** Dual of Support Vector Regression

# Solving Unconstrained Minimization Problem

- Intuitively: Minimize by setting derivative (gradient) to 0 and hoping to find **closed form** solution.
- When is such a solution a global minimum?
- For most optimization problems, finding closed form solutions is difficult. Even for linear regression (for which closed form solution exists), are there alternative methods?
  - Eg: Consider,  $\mathbf{y} = \phi\mathbf{w}$ , where  $\phi$  is a matrix with full column rank, the least squares solution,  $\mathbf{w}^* = (\Phi^T\Phi)^{-1}\Phi^T\mathbf{y}$ . Now, imagine that  $\phi$  is a very large matrix. with say, 100,000 columns and 1,000,000 rows. Computation of closed form solution might be challenging.
- How about iterative methods?

# Foundations: Level curves and surfaces

- A level curve of a function  $\mathbf{f}(\mathbf{x})$  is defined as a curve along which the value of the function remains unchanged while we change the value of its argument  $\mathbf{x}$ .
- Formally we can define a level curve as :

$$L_c(\mathbf{f}) = \left\{ \mathbf{x} \mid \mathbf{f}(\mathbf{x}) = \mathbf{c} \right\} \quad (1)$$

where  $c$  is a constant.

# Foundations: Level curves and surfaces

- Example of different level curves for a single function

Figure 1: 10 level curves for the function  $f(\mathbf{x}_1, \mathbf{x}_2) = x_1 e^{x_2}$  (Figure 4.12 from <https://www.cse.iitb.ac.in/~CS725/notes/classNotes/BasicsOfConvexOptimization.pdf>)

# Foundations: Directional Derivatives

- Directional derivative: Rate at which the function changes at a given point  $\mathbf{x}$  in a given direction  $\mathbf{v}$
- The *directional derivative* of a function  $f$  in the direction of a unit vector  $\mathbf{v}$  at a point  $\mathbf{x}$  can be defined as :

$$D_{\mathbf{v}}(f, \mathbf{x}) = \lim_{h \rightarrow 0} \frac{f(\mathbf{x} + h\mathbf{v}) - f(\mathbf{x})}{h} \quad (2)$$

$$\text{s.t. } \|\mathbf{v}\|_2 = 1 \quad (3)$$

- The **gradient vector** of a function  $f$  at a point  $\mathbf{x}$  is defined as:

$$\nabla f_{\mathbf{x}^*} = \begin{bmatrix} \frac{\partial f(\mathbf{x})}{\partial x_1} \\ \frac{\partial f(\mathbf{x})}{\partial x_2} \\ \cdot \\ \cdot \\ \frac{\partial f(\mathbf{x})}{\partial x_n} \end{bmatrix} \in \mathbb{R}^n \quad (4)$$

- **Magnitude (euclidean norm)** of gradient vector at any point indicates maximum value of directional derivative at that point
- **Direction** of gradient vector indicates direction of this maximal directional derivative at that point.

# Foundations: Gradient Vector

- The figure below illustrates the gradient vector for the same level curves

**Figure 2:** The level curves along with the gradient vector at  $(2, 0)$ . Note that the gradient vector is perpendicular to the level curve  $x_1 e^{x_2} = 2$  at  $(2, 0)$

# Hyperplanes

- A hyperplane in an  $n$ -dimensional Euclidean space is a flat,  $n-1$  dimensional subset of that space that divides the space into two disjoint half-spaces.
- Technically, a hyperplane is a set of points whose direction *w.r.t.* a point  $\mathbf{q}$  is orthogonal to a vector  $\mathbf{v}$ :

$$H_{\mathbf{v},\mathbf{q}} = \left\{ \mathbf{p} \mid (\mathbf{p} - \mathbf{q})^T \mathbf{v} = 0 \right\} \quad (5)$$

- **Tangential Hyperplane:** Plane orthogonal to the gradient vector at  $\mathbf{x}^*$ .

# Hyperplanes

- A hyperplane in an  $n$ -dimensional Euclidean space is a flat,  $n-1$  dimensional subset of that space that divides the space into two disjoint half-spaces.
- Technically, a hyperplane is a set of points whose direction *w.r.t.* a point  $\mathbf{q}$  is orthogonal to a vector  $\mathbf{v}$ :

$$H_{\mathbf{v},\mathbf{q}} = \left\{ \mathbf{p} \mid (\mathbf{p} - \mathbf{q})^T \mathbf{v} = 0 \right\} \quad (5)$$

- **Tangential Hyperplane:** Plane orthogonal to the gradient vector at  $\mathbf{x}^*$ .

$$TH_{\mathbf{x}^*} = \left\{ \mathbf{p} \mid (\mathbf{p} - \mathbf{x}^*)^T \nabla f(\mathbf{x}^*) = 0 \right\} \quad (6)$$

We recall that the problem was to find  $\mathbf{w}$  such that

$$\mathbf{w}^* = \arg \min_{\mathbf{w}} \|\Phi \mathbf{w} - \mathbf{y}\|^2 + \lambda \|\mathbf{w}\|^2 \quad (7)$$

$$= \arg \min_{\mathbf{w}} (\mathbf{w}^T \Phi^T \Phi \mathbf{w} - 2\mathbf{w}^T \Phi^T \mathbf{y} - \mathbf{y}^T \mathbf{y} + \lambda \|\mathbf{w}\|^2) \quad (8)$$

# Foundations: Gradient Vector

- Magnitude (euclidean norm) of gradient vector at any point indicates maximum value of directional derivative at that point
- Thus, at the point of minimum of a differentiable minimization objective (such as least squares for regression), ....

# Foundations: Necessary condition 1

- If  $\nabla f(\mathbf{w}^*)$  is defined &  $\mathbf{w}^*$  is local minimum/maximum, then  $\nabla f(\mathbf{w}^*) = 0$  (A necessary condition) (Cite : Theorem 60) of `CS725/notes/classNotes/BasicsOfConvexOptimization.pdf`
- Given that

$$f(\mathbf{w}) = \arg \min_{\mathbf{w}} (\mathbf{w}^T \Phi^T \Phi \mathbf{w} - 2\mathbf{w}^T \Phi^T \mathbf{y} - \mathbf{y}^T \mathbf{y} + \lambda \|\mathbf{w}\|^2)$$

$\implies \dots\dots\dots$

- We would have

$\dots\dots\dots$

$\implies \dots\dots\dots$

$\implies \dots\dots\dots$

# Foundations: Necessary condition 1

- If  $\nabla f(\mathbf{w}^*)$  is defined &  $\mathbf{w}^*$  is local minimum/maximum, then  $\nabla f(\mathbf{w}^*) = 0$  (A necessary condition) (Cite : Theorem 60) [CS725/notes/classNotes/BasicsOfConvexOptimization.pdf](#)
- Given that

$$f(\mathbf{w}) = \arg \min_{\mathbf{w}} (\mathbf{w}^T \Phi^T \Phi \mathbf{w} - 2\mathbf{w}^T \Phi^T \mathbf{y} - \mathbf{y}^T \mathbf{y} + \lambda \|\mathbf{w}\|^2) \quad (9)$$

$$\implies \nabla f(\mathbf{w}) = 2\Phi^T \Phi \mathbf{w} - 2\Phi^T \mathbf{y} + 2\lambda \mathbf{w} \quad (10)$$

- We would have

$$\nabla f(\mathbf{w}^*) = 0 \quad (11)$$

$$\implies 2(\Phi^T \Phi + \lambda I) \mathbf{w}^* - 2\Phi^T \mathbf{y} = 0 \quad (12)$$

$$\implies \mathbf{w}^* = (\Phi^T \Phi + \lambda I)^{-1} \Phi^T \mathbf{y} \quad (13)$$

# Foundations: Necessary Condition 2

- Is  $\nabla^2 f(\mathbf{w}^*)$  positive definite ?  
i.e.  $\forall \mathbf{x} \neq 0$ , is  $\mathbf{x}^T \nabla^2 f(\mathbf{w}^*) \mathbf{x} > 0$ ? (A sufficient condition for local minimum)  
(Note : Any positive definite matrix is also positive semi-definite)  
(Cite : Section 3.12 & 3.12.1)<sup>1</sup>

.....  
 $\implies$  .....  
.....  
.....

- And if  $\Phi$  has full column rank ,

.....

---

$$\therefore \text{If } \mathbf{x} \neq 0, \quad \mathbf{x}^T \nabla^2 f(\mathbf{w}^*) \mathbf{x} > 0$$

<sup>1</sup>CS725/notes/classNotes/LinearAlgebra.pdf

## Foundations: Necessary Condition 2

- Is  $\nabla^2 f(\mathbf{w}^*)$  positive definite ?

i.e.  $\forall \mathbf{x} \neq 0$ , is  $\mathbf{x}^T \nabla^2 f(\mathbf{w}^*) \mathbf{x} > 0$ ? (A sufficient condition for local minimum)

(Any positive definite matrix is also positive semi-definite)

(Cite : Section 3.12 & 3.12.1)<sup>2</sup>

$$\nabla^2 f(\mathbf{w}^*) = 2\Phi^T \Phi + 2\lambda I \quad (14)$$

$$\implies \mathbf{x}^T \nabla^2 f(\mathbf{w}^*) \mathbf{x} = 2\mathbf{x}^T (\Phi^T \Phi + \lambda I) \mathbf{x} \quad (15)$$

$$= 2 \left( (\Phi + \sqrt{\lambda} I) \mathbf{x} \right)^T \Phi \mathbf{x} \quad (16)$$

$$= 2 \left\| (\Phi + \sqrt{\lambda} I) \mathbf{x} \right\|^2 \geq 0 \quad (17)$$

- And with  $\lambda = 0$ , if  $\Phi$  has full column rank ,

$$\Phi \mathbf{x} = 0 \quad \text{iff} \quad \mathbf{x} = 0 \quad (18)$$

$\therefore$  If  $\mathbf{x} \neq 0$ ,  $\mathbf{x}^T \nabla^2 f(\mathbf{w}^*) \mathbf{x} > 0$

# Example of linearly correlated features

- Example where  $\Phi$  doesn't have a full column rank,

$$\Phi = \begin{bmatrix} x_1 & x_1^2 & x_1^2 & x_1^3 \\ x_2 & x_2^2 & x_2^2 & x_2^3 \\ \vdots & \vdots & \vdots & \vdots \\ x_n & x_n^2 & x_n^2 & x_n^3 \end{bmatrix} \quad (19)$$

- This is the simplest form of linear correlation of features, and it is not at all desirable.
- Effect of a nonzero  $\lambda$  with such  $\Phi$  is that

# Example of linearly correlated features

- Example where  $\Phi$  doesn't have a full column rank,

$$\Phi = \begin{bmatrix} x_1 & x_1^2 & x_1^2 & x_1^3 \\ x_2 & x_2^2 & x_2^2 & x_2^3 \\ \vdots & \vdots & \vdots & \vdots \\ x_n & x_n^2 & x_n^2 & x_n^3 \end{bmatrix} \quad (19)$$

- This is the simplest form of linear correlation of features, and it is not at all desirable.
- Effect of a nonzero  $\lambda$  with such  $\Phi$  is that it tends to make the Hessian more positive definite

# Do Closed-form solutions Always Exist?

- Linear regression and Ridge regression both have closed-form solutions

- For linear regression,

$$w^* = (\Phi^T \Phi)^{-1} \Phi^T y$$

- For ridge regression,

$$w^* = (\Phi^T \Phi + \lambda I)^{-1} \Phi^T y$$

(for linear regression,  $\lambda = 0$ )

- What about optimizing the formulations (constrained/penalized) of Lasso ( $L_1$  norm)? And support-based penalty ( $L_0$  norm)? **Also requires tools of Optimization/duality**
