## Signatures, Random Oracles

[Total 100 pts]

### 1. Attacking a Signature Scheme

[20 pts]

In this problem, we consider a seemingly minor modification of the Schnorr signature scheme, and show that it can be broken.

Recall that, in the original scheme, the verification key is  $(\mathbb{G}, g, Y)$ , where  $\mathbb{G}$  is a prime-order group with a generator  $g$  and  $Y = g^y$  is a random group element, with  $y \leftarrow \mathbb{Z}_{|\mathbb{G}|}$  being the signing key; the signature on a message  $M$  is produced as  $\text{Sign}_y(M) = (e, s)$ , where  $e = H(M || g^r)$  and  $s = r - ye$ , for a random  $r \leftarrow \mathbb{Z}_{|\mathbb{G}|}$ .

In the modified scheme the messages belong to  $\mathbb{G}$ , and  $e = H(M || g^r)$  is replaced by  $e = H(M \cdot g^r)$ .

Give an existential forgery attack on this modified scheme (in the random oracle model).

### 2. CCA Secure PKE in the Random Oracle Model

[40 pts]

Suppose  $(\text{KeyGen}, \text{Enc}, \text{Dec})$  is a CPA-secure PKE scheme. We shall write  $\text{Enc}_{PK}(m; r)$  to indicate encryption of the message  $m$  using randomness  $r$ ; suppose  $\text{Enc}$  requires  $r \leftarrow \{0, 1\}^k$  ( $k$ , as always, being the security parameter). Also, suppose  $H$  is a hash function modeled as a random oracle with  $k$ -bit outputs.

Consider a new encryption scheme with the encryption algorithm defined as follows:  $\text{Enc}_{PK}^*(m; r) = (\text{Enc}_{PK}(m || r; H(r)), H(m || r))$ , where  $r \in \{0, 1\}^k$ .

- (a) What should the corresponding decryption algorithm  $\text{Dec}^*$  be so that  $(\text{KeyGen}, \text{Enc}^*, \text{Dec}^*)$  is a CCA-secure encryption scheme?
- (b) Prove that with  $\text{Dec}^*$  as you defined above,  $(\text{KeyGen}, \text{Enc}^*, \text{Dec}^*)$  is indeed a CCA-secure encryption scheme in the random oracle model. Flesh out the details of the proof as much as you can, basing your arguments only on the CPA-security of the given scheme, and statistical properties.

*Hint: You should convert a CCA-adversary  $A^*$  for  $(\text{KeyGen}, \text{Enc}^*, \text{Dec}^*)$  into a CPA-adversary  $A$  for  $(\text{KeyGen}, \text{Enc}, \text{Dec})$ .  $A$  will need to simulate the random oracle and the decryption oracle that  $A^*$  expects. As such,  $A$  gets to see all random oracle queries that  $A^*$  makes.*

- (c) Show that the scheme will not even be CPA secure if  $H(m || r)$  is replaced by  $H(m)$ .
- (d) Show that, for some choice of a CPA-secure scheme  $(\text{KeyGen}, \text{Enc}, \text{Dec})$ , the modified scheme will not even be CPA secure if  $H(m || r)$  is replaced by  $H(r)$ .

### 3. 2-Universal Hash Function.

[20 pts]

For a prime number  $q$  and positive integers  $m, n$ , and  $R := \mathbb{Z}_q^n$ . Below, all probabilities refer to the uniformly random choice of  $\mathbf{L} \leftarrow \mathbb{Z}_q^{n \times m}$ , and all addition and multiplication of numbers are modulo  $q$ .

- (a) Suppose  $D = \mathbb{Z}_q^m \setminus \{0^m\}$ . Prove that  $\forall \mathbf{x} \in D, \mathbf{a} \in R, \Pr_{\mathbf{L}}[\mathbf{L}\mathbf{x} = \mathbf{a}] = 1/|R|$ .

*Hint: Fix an  $i$  s.t.  $\mathbf{x}_i \neq 0$ . Consider sampling  $\mathbf{L}$  by picking the  $i^{\text{th}}$  column last.*

- (b) Now suppose  $D = \{0, 1\}^m \setminus \{0^m\}$  (i.e., non-zero vectors with only 0 and 1 entries). Show that  $\forall \mathbf{x}, \mathbf{y} \in D$  s.t.  $\mathbf{x} \neq \mathbf{y}, \mathbf{a}, \mathbf{b} \in R, \Pr_{\mathbf{L}}[\mathbf{L}\mathbf{x} = \mathbf{a}, \mathbf{L}\mathbf{y} = \mathbf{b}] = 1/|R|^2$ .

*Hint: Argue that if  $\mathbf{x} \neq \mathbf{y}$  and  $\mathbf{x}, \mathbf{y} \in \{0, 1\}^m$  there are at least two coordinates  $i, j$  restricted to which  $\mathbf{x}, \mathbf{y}$  are linearly independent. Consider sampling  $\mathbf{L}$  by picking these two columns last.*

This shows that the family of functions  $\mathcal{H} = \{h_{\mathbf{L}} \mid \mathbf{L} \in \mathbb{Z}_q^{n \times m}\}$ , where  $h_{\mathbf{L}} : D \rightarrow R$  is defined as  $h_{\mathbf{L}}(\mathbf{x}) = \mathbf{L}\mathbf{x}$  is a 2-universal hash function when  $D = \{0, 1\}^m \setminus \{0^m\}$ . We can upgrade this to a 2-universal hash function family for  $D = \{0, 1\}^m$  (i.e., including the all-zero vector) by considering  $h_{\mathbf{L}, \mathbf{u}}(\mathbf{x}) = \mathbf{L}\mathbf{x} + \mathbf{u}$  over all  $(\mathbf{L}, \mathbf{u}) \in \mathbb{Z}_q^{n \times m} \times \mathbb{Z}_q^m$ .

#### 4. Needham-Schroeder Protocol.

[20 pts]

The Needham-Schroeder Public Key protocol was an early protocol (proposed in 1978) for “authenticated key exchange,” using a public-key “encryption” scheme. (This was well before Goldwasser and Micali had developed the CPA security notion for encryption.)

The protocol uses a trusted server,  $S$ , to help two parties exchange secret keys with each other. A priori, there are no secrecy or authentication guarantees on the communication network, and the parties know only each other’s identities and a public key of the server  $S$ . The server,  $S$ , knows public keys of all the users. The goal of the protocol is that at the end  $A$  and  $B$  should agree on random nonces  $N_A$  and  $N_B$  (chosen by  $A$  and  $B$  respectively).

The protocol is shown in Figure 1. It is described in terms of a public key “encryption” algorithm  $\text{Enc}$ . It is a *deterministic* encryption scheme with the property that  $\text{Enc}_{PK}(\text{Enc}_{SK}^{-1}(M)) = M$ . If  $M$  is sufficiently random,  $\text{Enc}_{SK}^{-1}(M)$  is assumed to behave like a (very weak) signature on  $M$ : it is infeasible for an adversary who is given a random  $M$  to create the signature on  $M$  (note that this is weaker than the notion of existential unforgeability, which is not satisfied by this scheme).  $PA, PB$  are Alice and Bob’s public keys and  $SA, SB$  are their secret keys, respectively. Likewise, the server’s public and secret keys are  $PS, SS$ .

$A \rightarrow S :$	$A, B$	(This is $A$ requesting $S$ to send $B$ ’s public-key)
$S \rightarrow A :$	$\text{Enc}_{SS}^{-1}(PB, B)$	( $A$ will use $\text{Enc}_{PS}$ to recover $B$ ’s public key)
$A \rightarrow B :$	$\text{Enc}_{PB}(N_A, A)$	(where $N_A$ is a fresh nonce, picked by $A$ )
$B \rightarrow S :$	$B, A$	(Now $B$ requests $S$ to send $A$ ’s public-key)
$S \rightarrow B :$	$\text{Enc}_{SS}^{-1}(PA, A)$	( $B$ will use $\text{Enc}_{PS}$ to recover $A$ ’s public key)
$B \rightarrow A :$	$\text{Enc}_{PA}(N_B, N_A)$	(where $N_B$ is a fresh nonce picked by $B$ )
$A \rightarrow B :$	$\text{Enc}_{PB}(N_B)$	( $A$ and $B$ agree on $N_A, N_B$ at this point)

Figure 1: The Needham-Schroeder public-key protocol.

- (a) There is a (famous) man-in-the-middle attack on this protocol, whereby a party  $E$  in the system can set up a shared key with  $B$ , such that  $B$  thinks that she has shared that key with  $A$ . Describe such an attack (without looking it up!).

*Hint: The adversary can run a concurrent session with  $A$ .*

- (b) Suggest a (small) fix for the attack.
- (c) If you were designing this protocol today, using public-key encryption and signatures, how would you do it? [Extra Credit]
