

Communication Protocols

Lecture 16

TLS

We saw...

- Symmetric-Key Components
 - SKE, MAC
- Public-Key Components
 - PKE, Digital Signatures
- Building blocks: Block-ciphers (AES), Hash-functions (SHA-3), Trapdoor PRG/OWP for PKE (e.g., DDH, RSA) and Random Oracle heuristics (in RSA-OAEP, RSA-PSS)
- Symmetric-Key primitives much faster than Public-Key ones
 - Hybrid Encryption gets best of both worlds

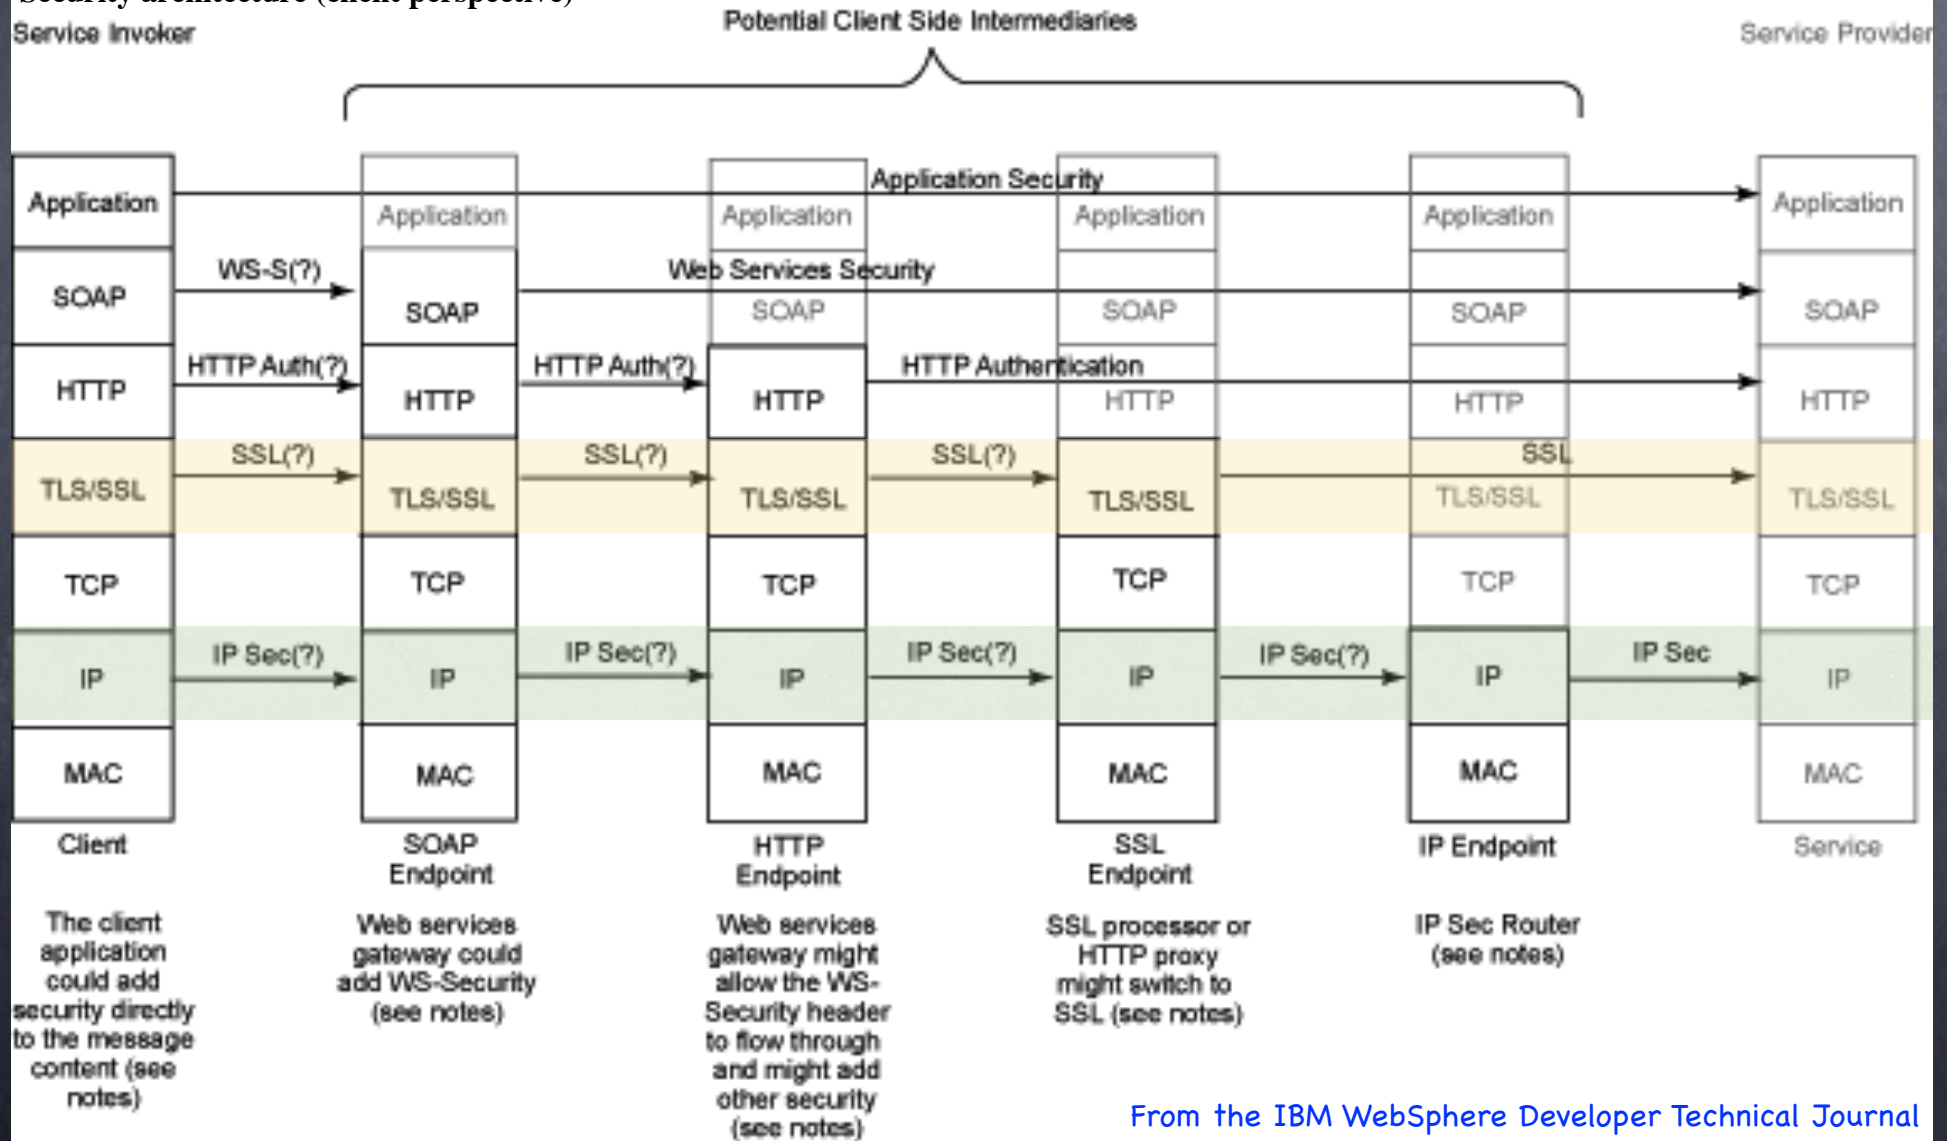

Secure Communication in Practice

- Can do at different levels of the “network stack”
 - e.g., “application layer”, “transportation layer” or “network layer”
- Protocol standards in all cases
 - To be interoperable
 - To not insert bugs by doing crypto engineering oneself
 - e.g.: SSL/TLS (used in https), IPSec (in the “network layer”)
 - Allows implementation in libraries or within OS kernels

Security Architectures

(An example)

Security architecture (client perspective)

TLS

- Transport Layer Security
 - Is “above” the transport layer provided by TCP/IP
- TLS can implement secure channels even if the lower layers of the network are adversarial
 - But if the network is arbitrarily adversarial, TLS cannot prevent Denial of Service
 - IPSec and authenticated versions of DNS and BGP to make the network less adversarial (next time)
 - Also, secure channels don't hide traffic (source/destination, rate of communication)

Secure Communication Infrastructure

- Goal: a way for Alice and Bob to setup a private and authenticated communication channel (can give a detailed SIM-definition)
- Simplest idea: **Use public-key encryption to send signed messages**

CCA Secure. Can use hybrid encryption.

Existentially unforgeable signatures. With a sequence number and channel ID to prevent replay/reordering.

- Limitation: Alice, Bob need to know each other's public-keys
- Also, room for efficiency improvements
 - Once a secret-key is setup, can use symmetric-key authenticated encryption instead of using signatures
 - If fresh PKE key in each authenticated session, only CPA security needed
 - Can maintain state (keys, counters) throughout the session

Secure Communication Infrastructure

- Secure Communication Sessions

- Handshake protocol: establish private shared keys

(Authenticated)
Key-Exchange

- Record protocol: use efficient symmetric-key schemes

- Server-to-server communication: Both parties have (certified) public-keys
- Client-server communication: server has (certified) public-keys
- Client “knows” server. Server willing to talk to all clients
- Client-Client communication (e.g., email)
Clients share public-keys in ad hoc ways

Server may “know” (some) clients too, using passwords, pre-shared keys, or if they have (certified) public-keys. Often implemented in application-layer

Certificate Authorities

- How does a client know a server's public-key?
 - Based on what is received during a first session? (e.g., first ssh connection to a server)
- Better idea: Chain of trust
 - Client knows a Certification Authority's public key (for signature)

Certificate Authorities

- How does a client know a server's public-key?
 - Based on what is received during a first session? (e.g., first ssh connection to a server)
- Better idea: Chain of trust
 - Client knows a Certification Authority's public key (for signature)
 - Bundled with the software/hardware
- Certification Authority signs the signature verification key of the server (possibly via a chain)
 - CA is assumed to have verified that the PK was generated by the "correct" server before signing
 - Validation standards: Domain/Extended validation

Forward Secrecy

- Servers have long term public keys that are certified
 - Would be enough to have **long term signature keys**, but in practice sometimes **long term decryption keys** too
 - Problem: if the long term decryption key is leaked, old communications are also revealed
 - Adversary may have stored (or even actively participated in) old sessions which it couldn't read earlier
 - Solution: Do a fresh secure key-exchange for each session (authenticated using signatures)
 - TLS 1.3 removes support for static keys (except for externally prepared Pre-Shared Keys)

A Simple Secure Communication Scheme

- Handshake
 - Client sends fresh session keys for MAC and SKE to the server **using SIM-CCA secure PKE**, with server's PK (i.e. over an unauthenticated, but private channel)
- For authentication only: use MAC
 - In fact, a "stream-MAC": To send more than one message, but without allowing reordering
- For authentication + encryption, encrypt-then-MAC ("stream" versions)
 - Or better, use Authenticated Encryption

Server's PK either trusted (from a previous session for e.g) or certified by a trusted CA, using a Digital Signature scheme

Does not have forward secrecy!
Not allowed in TLS 1.3

A Simple Secure Communication Scheme

- Handshake – with forward secrecy
 - Client sends first message of a **key exchange protocol** and server responds with the second message. Symmetric keys derived from the resulting secret.
- For authentication only: use MAC
 - In fact, a “stream-MAC”: To send more than one message, but without allowing reordering
- For authentication + encryption, encrypt-then-MAC (“stream” versions)
- Or better, use Authenticated Encryption

Server's message is authenticated, and can include additional data, encrypted using the newly defined key. Also, includes a certificate of its signature key.

Need to avoid replay attacks (infeasible for server to explicitly check for replayed ciphertexts)

Recall “inefficient” domain-extension of MAC: Add a sequence number (and a session-specific nonce) to each message before MAC'ing

MAC serves dual purposes of CCA security and authentication

TLS (SSL)

- Handshake – with forward secrecy
 - Client sends first message of a key exchange protocol and server responds with the second message. Symmetric keys derived from the resulting secret.
- For authentication only: use MAC
 - In fact, a “stream-MAC”: To send more than one message, but without allowing reordering
- For authentication + encryption, encrypt-then-MAC (“stream” versions)
- Or better, use Authenticated Encryption

Negotiations on protocol version, “cipher suites” for SKE (block-ciphers & hash), PKE & signature algorithms.

e.g. cipher-suite: RSA-OAEP for key-exchange, AES for SKE, HMAC-SHA256 for MAC
(In TLS 1.3, Auth. Enc.)

TLS 1.3 allows only Diffie-Hellman key-exchange followed by HKDF
(TLS 1.2 allows a non-forward secure key exchange using RSA PKE)

TLS 1.2 uses MAC-then-encrypt! Not CCA secure in general, but secure with stream-cipher (and CBC MAC).
TLS 1.3 uses AEAD.

Several details on closing sessions, session caching, resuming sessions, using pre-shared keys ...

TLS: Some Considerations

- Overall security goal: Authenticated and Confidential Channel Establishment (ACCE), or Server-only ACCE
- Handshake Protocol
 - Cipher suites are negotiated, not fixed → “Downgrade attacks”
 - Doesn’t use CCA secure PKE, but is overall CCA secure if error in decryption “never revealed” (tricky to ensure!)
- Record Protocol
 - Using MAC-then-Encrypt (as in TLS 1.2) is tricky:
 - CCA-secure when using SKE implemented using a stream cipher (or block-cipher in CTR mode) or CBC-MAC
 - But insecure if more information revealed on decryption fails
 - e.g., different times taken by MAC check (or different error messages!) when a format error in decrypted message
- TLS 1.3 uses easier to analyse protocols

TLS: Some Considerations

- Numerous vulnerabilities keep surfacing

FREAK, DROWN, POODLE, Heartbleed, Logjam, ...

And numerous unnamed ones: www.openssl.org/news/vulnerabilities.html

Listed as part of Common Vulnerabilities and Exposures (CVE) list: cve.mitre.org/

- Bugs in protocols

- Often in complex mechanisms created for efficiency

- Often facilitated by the existence of weakened “export grade” encryption and improved computational resources

- Also because of weaker legacy encryption schemes (e.g. Encryption from RSA PKCS#1 v1.5 — known to be not CCA secure and replaced in 1998 — is still used in TLS 1.2)

- Bugs in implementations

- Side-channels that are not originally considered

- Back-Doors (?) in the primitives used in the standards

TLS: Some Considerations

- Numerous vulnerabilities keep surfacing

FREAK, DROWN, POODLE, Heartbleed, Logjam, ...

And numerous unnamed ones: www.openssl.org/news/vulnerabilities.html

Listed as part of Common Vulnerabilities and Exposures (CVE) list: cve.mitre.org/

(Kenny Paterson & Thyla van der Merwe, Dec 2016)

Encryption from RSA PKCS#1 v1.5 — known to be not CCA secure and replaced in 1998 — is still used in TLS)

- Bugs in implementations
- Side-channels that are not originally considered
- Back-Doors (?) in the primitives used in the standards
