

# demand paging / swapping

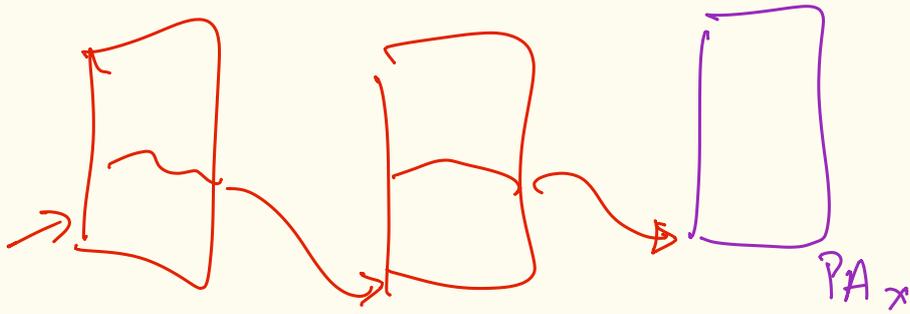

- ~ if no more / very less free PA pages
- copy / send some to (swap) disk
  - ~~copied~~ copied page now is a "free" page
  - can be reused for some other ~~or~~ V2P mapping.

VA<sub>x</sub> → page fault!

P<sub>1</sub>

P<sub>2</sub>

pte:

	valid	present
$\frac{V}{0}$	$\frac{P}{0}$	
$\frac{1}{0}$	$\frac{0}{0}$	
$\frac{0}{1}$	$\frac{1}{1}$	
$\frac{1}{1}$	$\frac{1}{1}$	

→ no v2p mapping in page table for offset of VA.

→ valid mapping but mapping not in memory

→ invalid

→ all good check permissions for access

swapped contents to disk.

- page fault w/  $V=1$  &  $P=0$

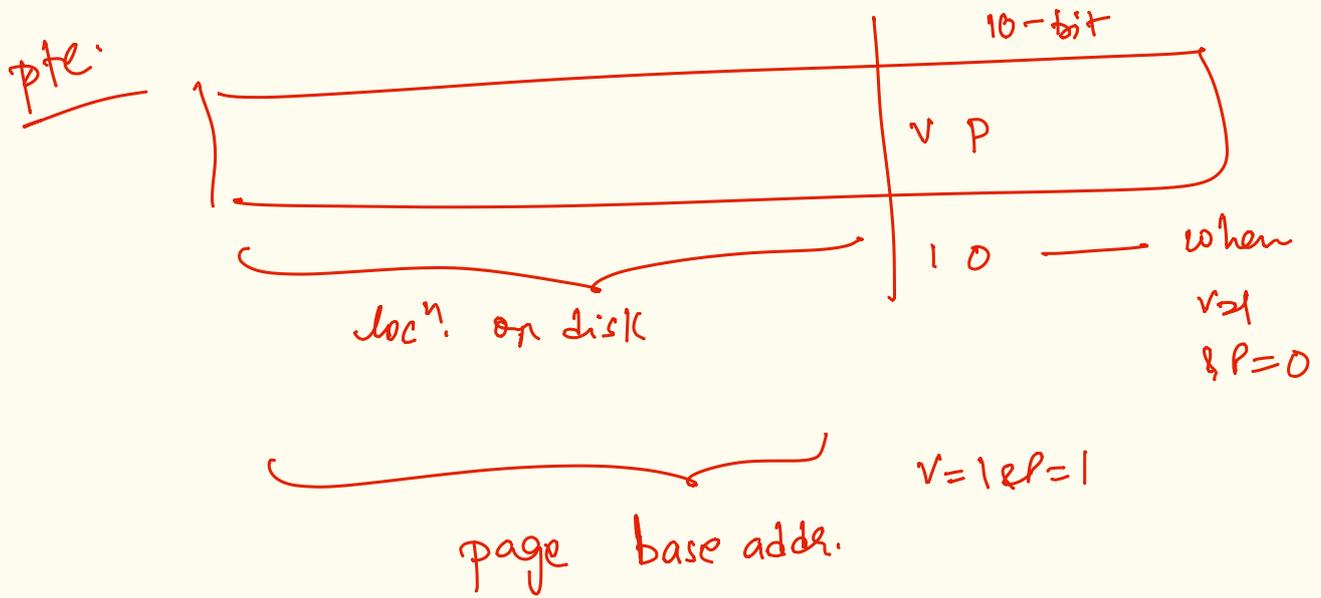

is diff. from  $V=0$  &  $P=0$

needs to - find content from disk

rides on free bits of PTE

- find a free page
- copy content to page

- update pagetable to point to free page
- set pte flags  $V=1$  &  $P=1$

pte flags :

D ~ dirty bit

A — accessed bit

on write to page updated

set on read by mmu

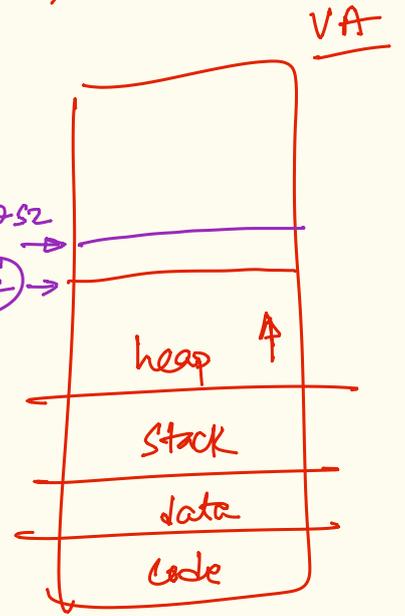

# # malloc & free

```
int * p = malloc (210 * size of int);
```

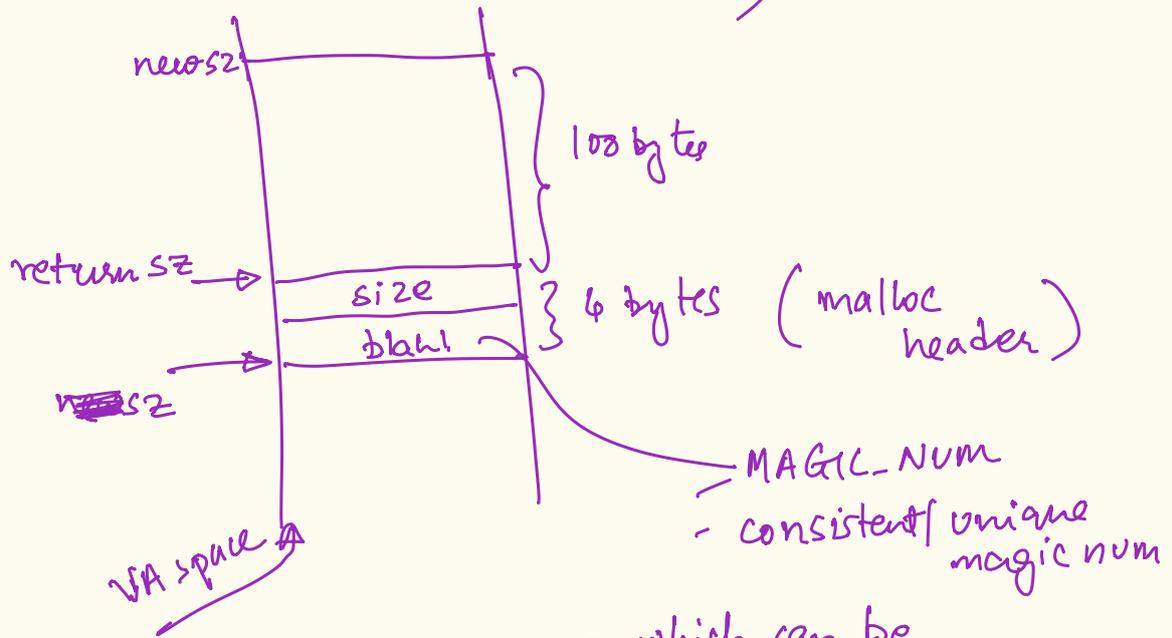

```
*p = 23;
```

```
free(p + 27);  
p = 2027
```

```
free(p) ← reset  
new sz  
back to sz
```

malloc (100) → strk ← system call (104)

```
*p-2 = 1e6;
```

- which can be read to validate free.
