# Static Slicing of Reactive Programs

**S. Ramesh**

Department of Computer Science and Engineering,  
Indian Institute of Technology Bombay,

Jointly with A. R. Kulkarni, Veritas India

**with support from Centre for Formal Design and Verification of  
Software, IIT Bombay**

## Program Slicing

- Functional Decomposition technique
- Ease of debugging, testing and understanding
- Formal Verification - recent interest
- Sequential Program Slicing (Weiser '84)
- Notion of slicing criterion:  $\langle pc, Var \rangle$
- Definition:  $slice(P)$  w.r.t.  $\langle pc, x \rangle$  is  $P'$  where,
  - $P'$  is obtained from  $P$  by removing some statements
  - If  $P$  reaches  $pc$  then  $P'$  also reaches  $pc$  and
  - $x$  has the same value in both  $P, P'$  at  $pc$ .
- Our focus is on Syntactic Static Slicing
- Other approaches: Dynamic, Semantic, Amorphous slicing

## Example:

Slicing Criterion:  $\langle \text{write}(\text{sum}), \text{sum} \rangle$

Entry

read(n)

i:=1

sum:=0

pro:=1

while i<=n

    sum:=sum+i

    pro:=pro\*i

    i:=i+1

end while

write(sum)

write(pro)

Exit

Entry

read(n)

i:=1

sum:=0

while i<=n

    sum:=sum+i

    i:=i+1

end while

write(sum)

Exit

## Issues

- Correctness: Slice includes **all** necessary statements
- Precision: **only** reqd. statements
- Only approximate slices possible (termination problem)
- $P$  itself a slice

## Computation of Slices

- Program Dependence Graph:
  - Control Dependence edges
  - Data Dependence edges
  - Example:

- Reachability Analysis

## Concurrent Program Slicing

- Cheng '97, Krinke '98, Gowri and Ramesh '00
- Slicing Criteria same
- More elaborate definition:
- Computation of Slices
  - Extended PDG - Threaded Program Dependence Graph (TPDG)
  - Example:

Home Page

Title Page

◀ ▶

◀ ▶

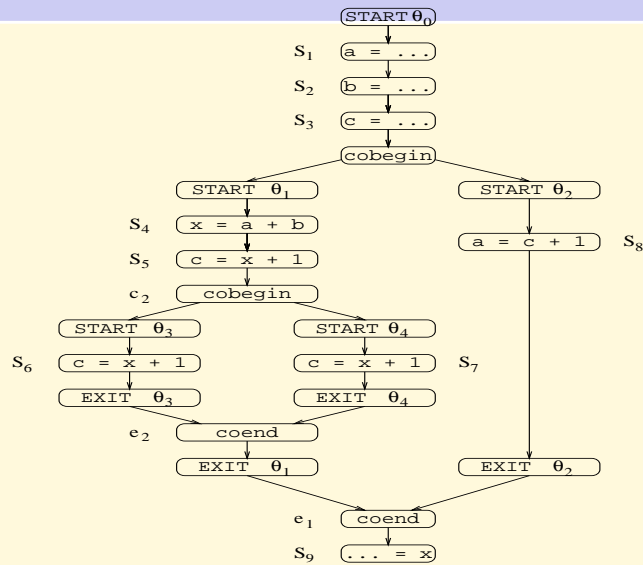

Page 7 of 38

(a) A threaded control flow graph (TCFG)

(b) The corresponding threaded program dependence graph (TPDG)

Figure 3.1: Representation of threaded programs

## Computation of Slices

- Naive reachability analysis is imprecise
- S4 is interference dependent upon S8 and S8 upon S5
- S4 not dependent upon S5
- Interference dependency is not transitive
- Refined reachability analysis
- Notion of **Trace Witness**  
 $(n_1, \dots, n_k)$  in the threaded PDG is a trace witness provided it forms a subsequence of some execution trace in the program.
- it is part of a valid execution trace
- Definition of Slice:

$$\text{Slice}(p) = \{q \mid q = n_1 \xrightarrow{d_1} n_2 \xrightarrow{d_2} \dots \xrightarrow{d_{k-1}} n_k = p, \\ d_i \in \{cd, dd, id\}, (n_1, \dots, n_k) \text{ is a trace witness}\}$$

## Computation of Slices

- Sophisticated traversal algorithm
- Traversal carries information about nodes already visited in each thread
- Original algorithm due to Krinke.
- Does not work when threads are inside the loop
- inaccurate slices
- Data dependence to be classified as direct and loop-carried dependence

## Slicing Algorithm

- state of execution recorded in tuple  $[t_0, t_1, \dots, t_n]$
- performs a backward traversal of TPDG
- for nodes  $y$  reached via edge  $y \rightarrow x$ :
  - data or control dependence: add  $y$  to slice. update tuple.
  - interference dependence:
    - \*  $t =$  last node visited in  $y$ 's thread
    - \* if trace witness exists for  $\langle y, t \rangle$ , add  $y$ . update tuple.
  - loop-carried data dependence: add  $y$  to slice. update tuple.

## Complexity

- Exponential on the number of threads (in theory)
- Many optimisations possible (in practice)
- Inter-procedural slicing
- Nontrivial extension
- Implemented Java Slicer (Gowri's thesis)

## Other works:

- slicing Promela (Millett, Teitelbaum '98)
- VHDL slicing (Clarke et al. '99)
- concurrency issues not addressed properly

## Slicing Synchronous Reactive Programs

- Reactive programs are ones that maintain continuous interaction with the environment
- Contrast with transformational programs
- Termination is a bad behaviour
- Examples of reactive systems:
  - Operating systems functions
  - Hardware
  - Embedded Controllers

## An Example

- ” Five seconds after the key is turned on, if the belt has not been fastened, an alarm will beep for five seconds or until the key is turned off ”

## An Esterel Solution

```
module belt_control:
input reset, key_on, key_off, belt_on,
    end_5, end_10;
output alarm(boolean), start_timer;
loop
  abort
  emit alarm(false);
  every key_on do
    abort
    emit start_timer;
    await end_5;
    emit alarm(true);
    await end_10;
    when [key_off or belt_on];
    emit alarm(false);
  end
  when reset
end.
end.
```

## Reactive Programs

- reactive programs are event-oriented
- time or event ordering need to be preserved
- Events are more fundamental than program control points

## Esterel

- a well-known language for programming embedded control programs
- used in avionics (Aerospatiale), DSP chips (TI France)
- Control flow quite different -back and forth from the environment and program

## Esterel Execution Model

- execution is a series of **reactions**.
- invoked from an external 'main' program repeatedly at discrete points of time
- one reaction per invocation
- control returns after each reaction

## Esterel Constructs

- many novel features
  - imperative paradigm, synchronous concurrency.
  - delay statements
  - instantaneous execution
  - Signal handling statements
  - Preemption and Exception handling statements
  - rich in control constructs:
    - \* preemption: `abort p when S`
    - \* suspension: `suspend p when S`
    - \* exception handling: `trap and exit`
  - Concurrent statements (synchronous concurrency)
  - Communication via broadcast signals
- Challenge for standard program analysis techniques

## Synchronous Parallelism

```
[stat1 || stat2 || stat3]
```

- simultaneous (not concurrent) execution of all the statements
- signals are used for communication
- signal emitted by one thread is **broadcast** to all other threads
- terminates when every `stati` terminates
- no sharing of variables
- compare with asynchronous parallelism

### Example:

```
[ emit S  
  || present S then emit O1 else emit O2  
  || present S then emit O3 else emit O4  
]
```

**S, O1 and O3 are simultaneously executed**

## Preemption Statements

strong abort

`abort stat when S`

- watchdog primitive
- The body `stat` is executed only when `S` is not present
- Presence of `S` instantaneously ‘kills’ the body
- No statement in `stat` is executed when `S` is present
- terminates either when either `stat` terminates or when `S` is present

Home Page

Title Page

Page 22 of 38

Go Back

Full Screen

Close

Quit

## Example:

```
abort
  pause;
  emit S1;
  pause;
  emit S2
when S
```

- emits S1 in the second instant and S2 in third instant if S is not present during these instants.
- if S is present in second instant then nothing happens; the whole statement exits.
- if S is not present in second instant and present in third instant then S1 is emitted in the second instant, terminates in the third instant; no S2 is emitted in the third instant
- S in the first instant is ignored S in the first instant is not ignored if you write `abort stat when immediate S`

Home Page

Title Page

Page 23 of 38

Go Back

Full Screen

Close

Quit

## Traps and exits

```
trap T in
  stat1
handle T do
  stat2
end trap
```

- Weak preemption primitive
- The body `stat1` may contain exit statement  
`exit T`
- execution starts with execution of `stat1`
- when `exit T` is encountered the control jumps to the `handle` statement
- `handle` statement is optional - control then returns to the statement following the `trap` statement
- if `stat1` is terminated then the whole trap statement is exited - `stat2` is not executed

## Slicing Reactive Programs

- Traditional slicing criterion not very natural
- Proposal for a new criterion
- Slicing Criterion:  $b$ , an output signal
- Slice of  $P$  w.r.t to  $b$  has the same ongoing behaviour as  $P$  as far as signal  $b$  is concerned
- That is,  $b$  is present in a computation of  $P$  iff it is present in a computation of  $Slice(P)$
- $Slice(P)$  obtained from  $P$ , by removing statements
- More generally,  $\langle S, b \rangle$ ,  $S$ , a state(ment) and  $b$  a signal
- Slice of  $P$  w.r.t  $\langle S, b \rangle$  preserves behaviour w.r.t.  $b$  in all computations that reach state(ment)  $S$ .

Home Page

Title Page

Page 25 of 38

Go Back

Full Screen

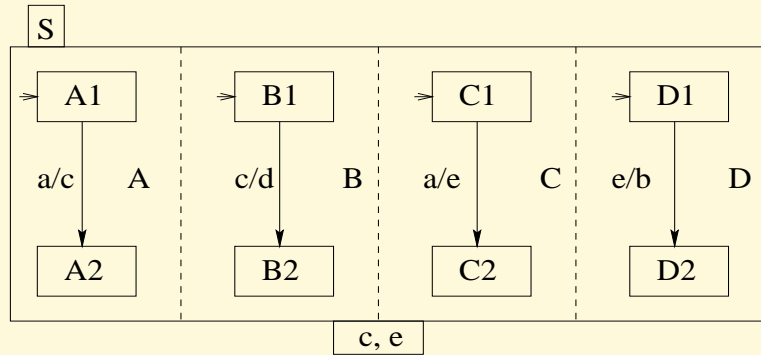

Close

Quit

## Formal Definition:

- $M$ , reactive program
- $M_s$  is the slice w.r.t  $\langle S, b \rangle$  iff
  - $M_s$  is obtained by removing zero or more states of  $M$  and
  - $\forall \sigma$ , sequence of input signals
    - \*  $(M[\sigma]/b) = (M_s[\sigma]/b)$
  - $M[\sigma]$ , output sequence produced by  $M$  on input  $\sigma$
  - $M[\sigma]/b$ , sequence restricted to only  $b$ .
- Useful for formal verification

## Example: An Argos Example

- Slice w.r.t  $b$ :
- Slice has the same behaviour as the original program as far as  $b$

## Computing Slices

- **Inadequacy of classical dependency**
- Very many new dependencies in Esterel
- interference control dependency (arises due to trap statements)
- time dependency (due to pause statement)
- dependency graph is generalised
- Synchronous Threaded Program Dependency Graph (STPDG)

# Exit

```
trap T
  X1 ;
  X2 ;
  present S then
    exit T
  end ;
  emit Y ;
end
```

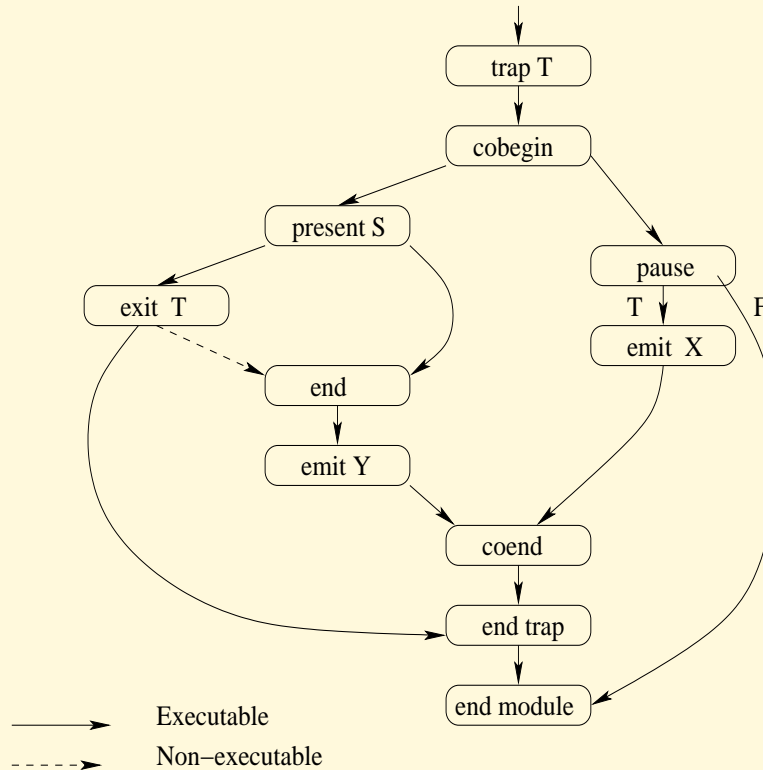

→ Executable  
- - - Non-executable

## Interference Control Dependence

**control dependence defn:**  $j$  control dependent on  $i$  iff:

- $j$  does not post dominate  $i$
- $\forall k$  along path  $i$  to  $j$ ,  $j$  post dominates  $k$ .

## Dependencies in Esterel

- data dependencies: cannot exist across threads in Esterel.
- signal dependencies – three types:
  - simple: exist in non-concurrent threads
  - loop-carried: actually loop-carried, and cross thread boundaries
  - interference: in concurrent threads
- control dependencies – two types:
  - induced in non-concurrent threads
  - induced in concurrent threads, because of preemption
- time dependencies – captured as control dependencies.

## STPDG

- Synchronous Threaded Program Dependence Graphs
- Slicing involves traversal along this graph
- Notion of Synchronous Trace Witness
- A path in the graph that is a possible execution sequence in the program
- Slice definition:

$$\begin{aligned}
 \text{Slice}(s) = \{ q \mid & \Gamma = \langle n_1, n_2, \dots, n_k \rangle, \\
 & q = n_1 \xrightarrow{d_1} \dots \xrightarrow{d_{k-1}} n_k = p, \\
 & p \text{ is a 'emit s' or 'sustain s' node,} \\
 & d_i \in E_{dd} \cup E_{cd} \cup E_{td} \cup E_{ssd} \cup \\
 & \quad E_{isd} \cup E_{icd}, 1 \leq i < k, \\
 & \Gamma \text{ is a trace witness in } G \}
 \end{aligned}$$

## Slicing Algorithm for Esterel

- slicing criterion =  $\langle \text{output signal} \rangle$
- state of execution recorded in tuple  $[t_0, t_1, \dots, t_n]$
- performs a backward traversal of TPDG
- for nodes  $y$  reached via edge  $y \rightarrow x$ :
  - data, control, simple signal dependence: add  $y$  to slice. update tuple.
  - interference signal or control dependence:
    - \*  $t =$  last node visited in  $y$ 's thread
    - \* if trace witness exists for  $\langle y, t \rangle$ , add  $y$ . update tuple.
  - loop-carried signal dependence: add  $y$  to slice. update tuple.

## Conclusions

- A New definition of slicing natural for reactive programs.
- Novel dependency graph representation
- A preliminary slicer for Esterel
- Same idea used for other reactive languages
- Slicers for Argos (Statecharts), VHDL
