

Implementation of WiFiRe PHY Sectorization in OPNET

P Sreedhar Reddy
Roll No. 06305024

24th July, 2007

Under the Guidance Of
Prof. Sridhar Iyer

Department Of Computer Science and Engineering
Indian Institute Of Technology, Bombay

Outline

- ▶ WiFiRe overview.
- ▶ WiFiRe model design in OPNET
- ▶ Simulation results of WiFiRe model design.
- ▶ Conclusion and future work.

System Architecture

- ▶ WiFiRe adopts star network topology.
- ▶ System is designed to cover cell with radius 15-20Km
- ▶ Cell is divided into sectors.
- ▶ System S consists of set of BSs
- ▶ ST antenna is directional which minimizes co-channel interference

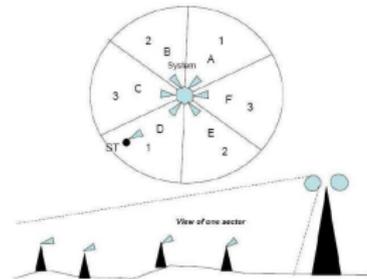

Figure: WiFiRe Network Configuration

Sectorization and frame structure

- ▶ Downlink and Uplink transmissions in a sector.
- ▶ WiFiRe employs TDD-MSTDM scheduling of slots
- ▶ Time is divided in to Frames

Protocol phases

- ▶ Network entry and initialization
 - ▶ Ranging
 - ▶ Registration

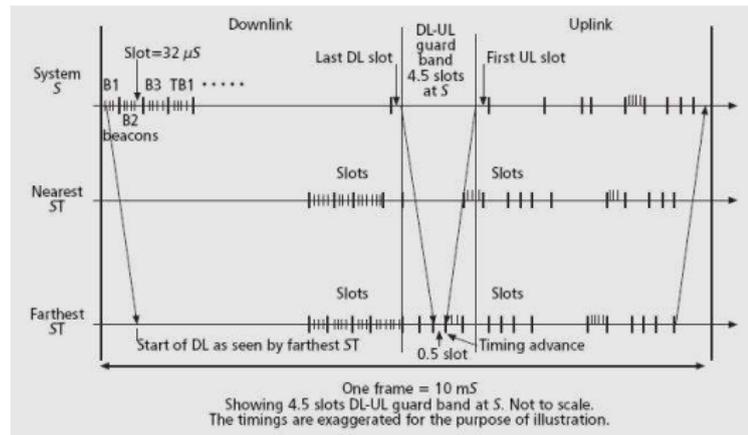

Figure: Uplink Downlink frame timings

MAC services

- ▶ UGS, pre-allocates periodic transmission opportunities to the STs, which eliminates the overhead involved in the bandwidth request-grant process. Used for fixed size periodic transmission such as VoIP.
- ▶ rtPS, ensures that STs get periodic bandwidth request opportunities. The STs can then request bandwidth from the BS.
- ▶ nrtPS, designed to support high bandwidth connections and not delay sensitive, which require variable size data grant slots on a regular basis, such as high bandwidth FTP.
- ▶ Best Effort service targets best effort traffic where no throughput or delay guarantees are necessary. These flows served in contention slots.

Prior work done on WiFiRe

Initial contributions 1

- ▶ Implemented some Base station, Subscriber station specific functionalities like processing control packets, beacon processing etc.
- ▶ Greedy heuristic scheduler at Base station with optimization parameter of UGS grant size of subscriber station.

Initial contributions 2

- ▶ Implemented WiMAX MAC model modifying for WiFiRe
- ▶ Modelled Polling, Bandwidth request mechanisms to simulate rtPS and nrtPS flows
- ▶ Modelled Round robin scheduler to accept various flows.

WiFiRe model design

Overview of work done earlier

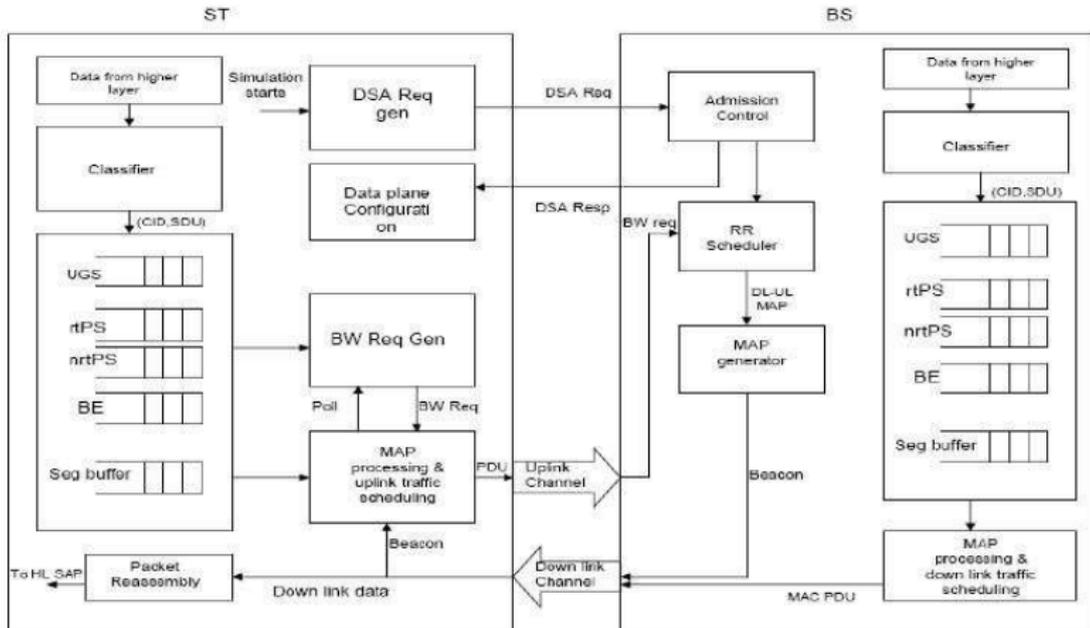

Figure: WiFiRe model design

WiFiRe Common MAC process model

Common functionalities to ST and BS

- ▶ segmentation and reassembly
- ▶ Beacon processing
- ▶ packet classification

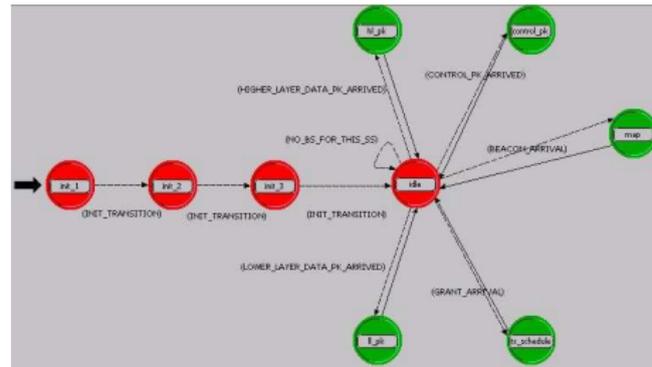

Figure: WiFiRe common MAC process

ST child control process

- ▶ ST child control process responsible for, DSA req, DSA response

Base child control process

- ▶ sending beacon periodically
- ▶ Processing DSA request
- ▶ Sending DSA response
- ▶ Scheduling downlink traffic

Present Work

Subscriber node model

- ▶ All STs have same MAC process
- ▶ MAC process responsible for defining service flows, processing beacons
- ▶ Each ST is modelled with directional antenna pointed towards system S

Base station node model

- ▶ BS node model consists of 6 WiFiRe interfaces, each WiFiRe interface represents a sector.
- ▶ Each WiFiRe interface is connected to antenna through transmitter and receiver.

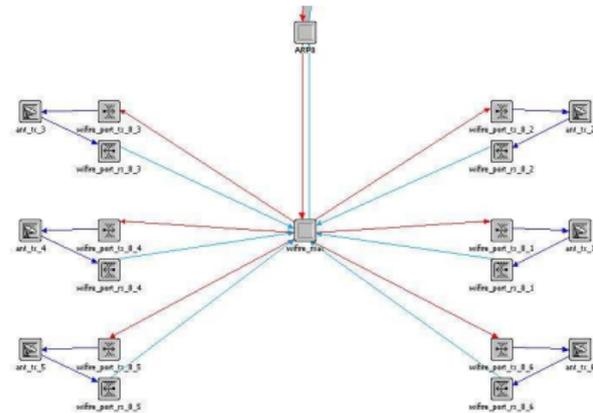

Figure: WiFiRe BS Node Model

Antenna object with transmitter and receiver

- ▶ Radio receiver and Radio transmitter are entry and exit points of packets through wireless environment via antenna object
- ▶ Antennas are used for modeling radio transmission
- ▶ Antenna pattern editor allow modeling of directional gain at radio receivers and transmitters

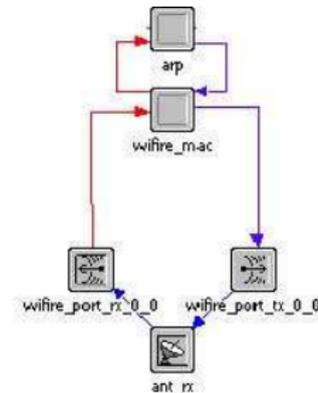

Figure: Antenna object with Tx and Rx

Antenna pattern

- ▶ Antenna pattern is defined in terms of spherical angle phi and theta
- ▶ Phi is horizontal angle
 - ▶ If $\phi = 0$ then the point is on the positive z-axis
 - ▶ If $\phi = \pi / 2$ then the point is in the xy-plane
 - ▶ if $\phi = 180$ then the point is on the negative z-axis
- ▶ Theta measures the angle from the positive xz-plane to the point.
- ▶ 3D antenna pattern is collection of 2D slices.
- ▶ Slices used for defining gain pattern

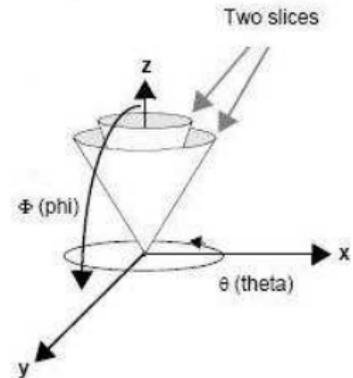

Figure: Antenna pattern using spherical angle phi and theta

Antenna pattern editor

- ▶ Antenna pattern editor is used for antenna pattern
- ▶ For each 2D slice, abscissa is theta and ordinate is associated gain
- ▶ Gain tables are created for 2D slices by sample points
- ▶ For n slices there are 2n sample points

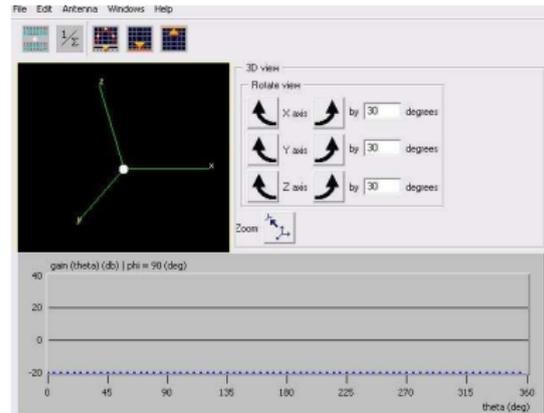

Figure: Antenna pattern editor for creating antenna pattern

Antenna Pointing processor module

- ▶ Each antenna is associated with processor module.
- ▶ Calculates the information that antenna needs to point at target.
- ▶ Convert node's position in to subnet
- ▶ Associates receiver node with transmitter in the subnet through antenna object
- ▶ Processor module makes calculation using Kernal procedures.

```

/* op_topo_parent() uses the processor object ID to determine the
/* processor's parent object ID. */

rx_node_id = op_topo_parent (op_id_self ());
subnet_id = op_topo_parent (rx_node_id);
tx_node_id = op_id_from_name (subnet_id, OPC_OBJTYPE_NDFIX, "tx");
comp_code = op_ima_obj_pos_get (tx_node_id, &latitude, &longitude,
&altitude, &x_pos, &y_pos, &z_pos);
rx_ant_id = op_id_from_name (rx_node_id, OPC_OBJTYPE_ANT, "ant_rx");
  
```

Figure: Processor module code snippet

Pipeline stages

- ▶ Exists between radio transmitter and radio receiver.
- ▶ Implements physical layer characteristics of wireless medium.
- ▶ Executed once for each packet transmission.
- ▶ TDA's for communication between pipeline stages

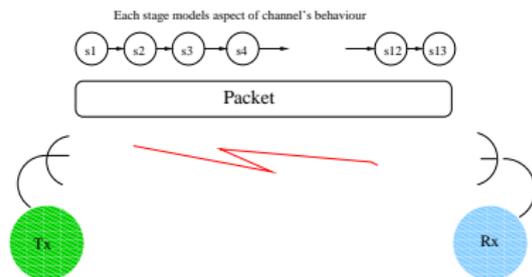

Figure: Transmission of packet

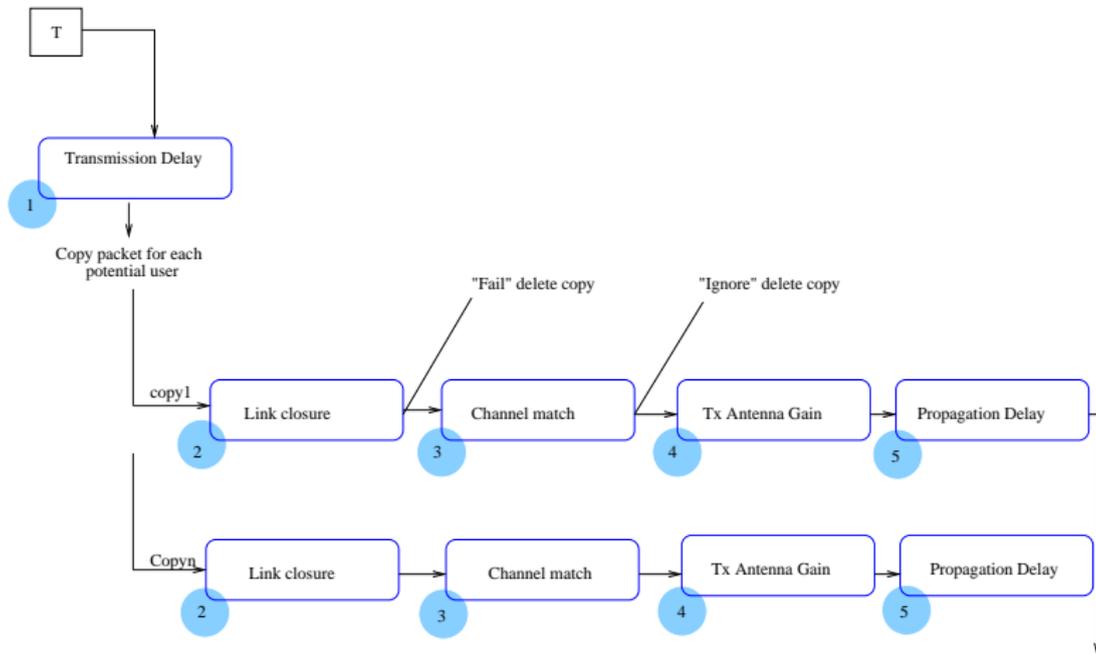

Figure: Transmitter pipeline stages

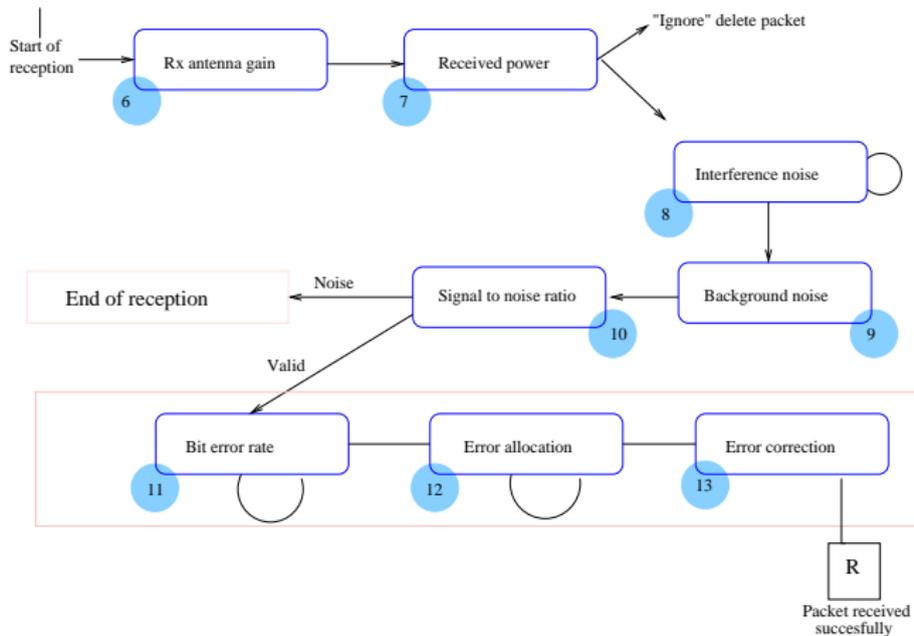

Figure: Receiver pipeline stages

Transmission delay

- ▶ Calculate the time for the entire packet transmission
- ▶ Active the trace to check the labelled break point is achieved
- ▶ Get transmission data rate from the packet using KP
- ▶ Place the result in Transmission data attributes for use of latter stages

```

if (op_prg_odb_ltrace_active ("sree"))
    op_prg_odb_print_minor ("reached transmission delay", OPC_NIL);
op_prg_odb_bkpt ("sree_test_bk_pt");
/*code by sree*/
op_pk_nfd_get_dbl (pkptr, "Tx Data Rate", &tx_rate);
/* Obtain length of packet. */
pklen = op_pk_total_size_get (pkptr);
/* Compute time required to complete transmission of packet */
tx_delay = pklen / tx_rate;
op_td_set_dbl (pkptr, OPC_TDA_RA_TX_DELAY, tx_delay)
  
```

Figure: Transmission delay code snippet

Channel match stage

- ▶ Active the trace to check labelled break point is achieved.
- ▶ Check for non overlapping bands for classification.
- ▶ Place the result in Transmission data attributes for use of latter stages

```

if (op_prg_odb_ltrace_active ("sree_test"))
    op_prg_odb_print_minor ("reached channel match pipeline stage", OPC_NIL);
op_prg_odb_bkpt ("sree_test_bk_pt");
/* Obtain transmitting channel attributes. */
tx_freq      = op_td_get_dbl (pkptr, OPC_TDA_RA_TX_FREQ);
tx_bw        = op_td_get_dbl (pkptr, OPC_TDA_RA_TX_BW);
/* Obtain receiving channel attributes. */
rx_freq      = op_td_get_dbl (pkptr, OPC_TDA_RA_RX_FREQ);
rx_bw        = op_td_get_dbl (pkptr, OPC_TDA_RA_RX_BW);
if ((tx_freq >= rx_freq + rx_bw) || (tx_freq + tx_bw <= rx_freq))
op_td_set_int (pkptr, OPC_TDA_RA_MATCH_STATUS, OPC_TDA_RA_MATCH_IGNORE);
if ((tx_freq != rx_freq) || (tx_bw != rx_bw))
op_td_set_int (pkptr, OPC_TDA_RA_MATCH_STATUS, OPC_TDA_RA_MATCH_NOISE);
  
```

Figure: Channel match stage code snippet

Transmitter antenna gain

- ▶ Compute the gain associated with the transmitter's antenna.
- ▶ Get all the transmitter geocentric coordinates of transmitter.
- ▶ perform difference vector from the transmitter to receiver.
- ▶ Place the result in Transmission data attributes for use of latter stages

```

/** Compute the gain associated with the transmitter's antenna. */
/* Obtain the geocentric coordinates of the transmitter. */
tx_x = op_td_get_dbl (pkptr, OPC_TDA_RA_TX_GEO_X);
tx_y = op_td_get_dbl (pkptr, OPC_TDA_RA_TX_GEO_Y);
tx_z = op_td_get_dbl (pkptr, OPC_TDA_RA_TX_GEO_Z);
/* Compute the vector from the transmitter to the receiver. */
    dif_x = rx_x - tx_x;
    dif_y = rx_y - tx_y;
    dif_z = rx_z - tx_z;
/* converts antenna direction to gain value corresponding to that direction*/
    gain = op_tbl_pat_gain (pattern_table, rx_phi, rx_theta);
/* Set the tx antenna gain in the packet's transmission data attribute. */
op_td_set_dbl (pkptr, OPC_TDA_RA_TX_GAIN, gain);
  
```

Figure: Transmitter antenna gain code snippet

Propagation delay

- ▶ Get distance between transmitter and receiver using TDA
- ▶ Propagation velocity is set to propagation velocity of radio signal.
- ▶ Calculate propagation delay using propagation velocity and propagation distance
- ▶ The result is placed in the propagation delay TDA

```
/** Compute the propagation delay between the transmitter and receiver**/  
/* Get the distance between transmitter and receiver. */  
prop_distance = op_td_get_dbl (pkptr, OPC_TDA_RA_START_DIST);  
/* Compute propagation delay to start of reception. */  
prop_delay = prop_distance / PROP_VELOCITY;  
op_td_set_dbl (pkptr, OPC_TDA_RA_START_PROPDEL, prop_delay)
```

Figure: Propagation delay code snippet

Received power

- ▶ Compute the received power of the arriving packet
- ▶ Correct reception of packet is determined by channel match.
- ▶ Depends on path loss, transmission frequency, transmitter and receiver antenna gain.
- ▶ Result is placed in TDA for use of latter stages.

Interference noise

- ▶ Account for the situation that two packets arrive concurrently at the same receiver channel
- ▶ Increment the number of collisions for two packets
- ▶ Interference of previous packet on arriving one is calculated and placed in TDA.

Signal to noise ratio

- ▶ Receive the rcvd power and interference noise from previous stages
- ▶ Calculated snr using received power and noise in db

```

/** Compute the signal-to-noise ratio for the given packet. */
/* Get the packet's received power level. */
rcvd_power = op_td_get_dbl (pkptr, OPC_TDA_RA_RCVD_POWER);
if (op_prg_odb_ltrace_active ("sree"))
    op_prg_odb_print_minor ("reached snr", OPC_NIL);
op_prg_odb_bkpt ("sree_test_bk_pt");
/*code by sree*/
/* Get the interference noise from previous stage */
accum_noise = op_td_get_dbl (pkptr, OPC_TDA_RA_NOISE_ACCUM);
/*Assign Snr in dB */
op_td_set_dbl (pkptr, OPC_TDA_RA_SNR, 10*log10(rcvd_power/(accum_noise)))
  
```

Figure: Signal to noise ratio code snippet

Bit error rate

- ▶ From Modulation scheme of Bit rate and SNR it calculates bit error rate
- ▶ Bit error rate is placed in BER Transmission date attribute
- ▶ Determine whether or not the arriving packet can be accepted

```

/* Determine current value of Signal-to-Noise-Ratio (SNR). */
    if (op_prg_odb_ltrace_active ("sree"))
        op_prg_odb_print_minor ("reached ber", OPC_NIL);
op_prg_odb_bkpt ("sree_test_bk_pt");
snr = op_td_get_dbl (pkptr, OPC_TDA_RA_SNR);
/* Derive expected BER from effective SNR. */
ber = op_tbl_mod_ber (modulation_table, snr);
/* Place the BER in the packet's transmission data. */
op_td_set_dbl (pkptr, OPC_TDA_RA_BER, ber);

```

Figure: Bit error rate code snippet

Experiments

- ▶ Building WiFiRe model in OPNET.
- ▶ Setup a sector using directional antenna.
- ▶ Setup STs in six sectored system with VoIP configuration
- ▶ Experiment to simulate VoIP and Video scenario

S.No	Parameter	Value
1	Data Rate	11 Mbps
2	Control packet data rate	2 Mbps
3	Frame Duration	10 ms
4	Slot duration	32 μ sec
5	DL-UL ratio	2:1
7	Service class	UGS

Table: System setup parameters

S.No	Parameter	Value
1	Frequency Channel	2.4 GHz
2	Bandwidth	22 MHz
3.	Duplexing technique	TDD
4.	PHY overhead	96 μ sec
5.	Number of symbols/frame	220000
6.	Symbol duration	0.045 μ sec

Table: PHY profile setup parameters

Setup to perform range of sectorization using directional antennas

Purpose of this experiment to show the sectorization works

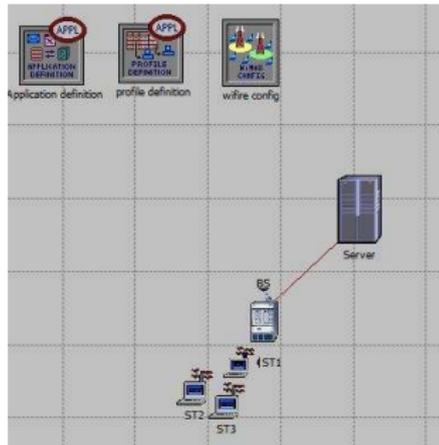

Figure: Scenario 1 with unit distance of 5Km

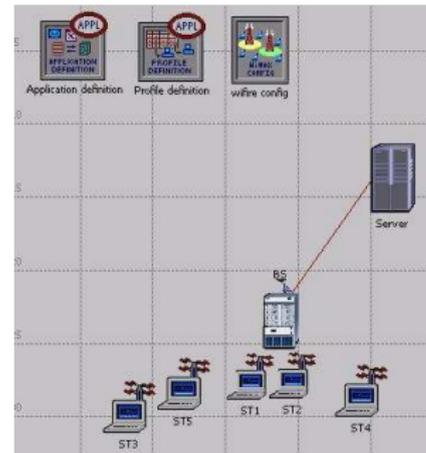

Figure: Scenario 2 with unit distance of 5Km

Above scenarios has setup of 60 degrees sectorized antenna at base station

Performance plots for range of sectorization

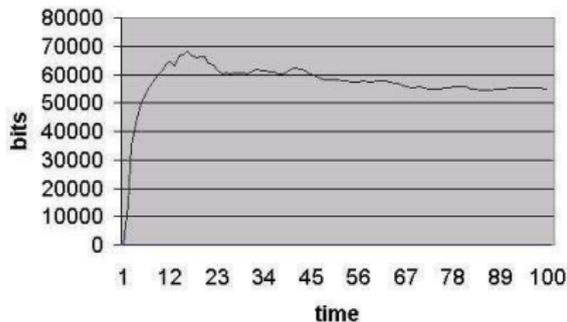

Figure: Load for scenario 1

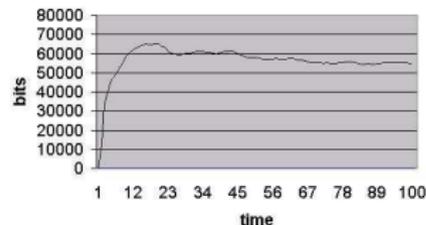

Figure: Throughput for scenario 1

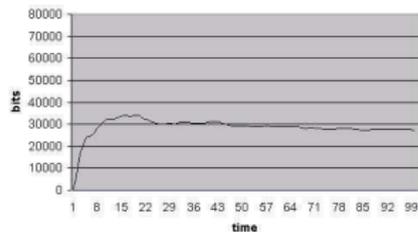

Figure: Throughput for scenario 2

Throughput of sectorization using directional antennas

- ▶ Each ST is requested with 20Kbps
- ▶ The total load offered with first scenario is 60Kbps.
- ▶ The total load offered with second scenario is 100Kbps.
- ▶ Throughput for first scenario with 3 STs is same as load due to proper sectorization of BS with respect to directionality of ST.
- ▶ The load offered for scenario 2 is 100Kbps.
- ▶ Throughput for Scenario 2 is less compared with load as some STs in this scenario are out of range in the sector.

Sectorized deployed in a sector using antenna pattern

Experiment to simulate VoIP calls

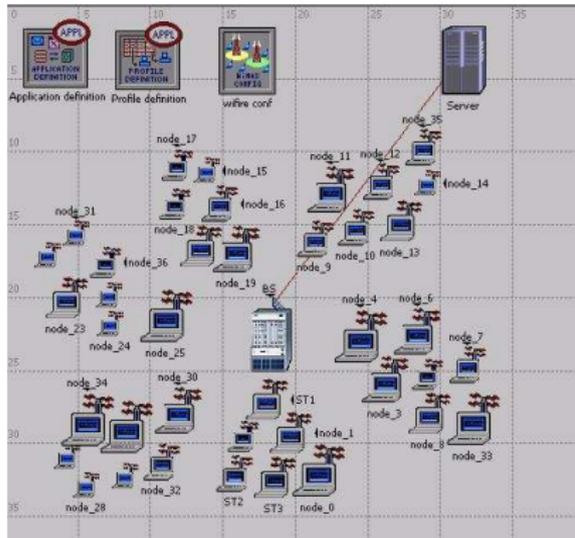

Figure: Scenario with 40 STs and unit distance of 5 Km

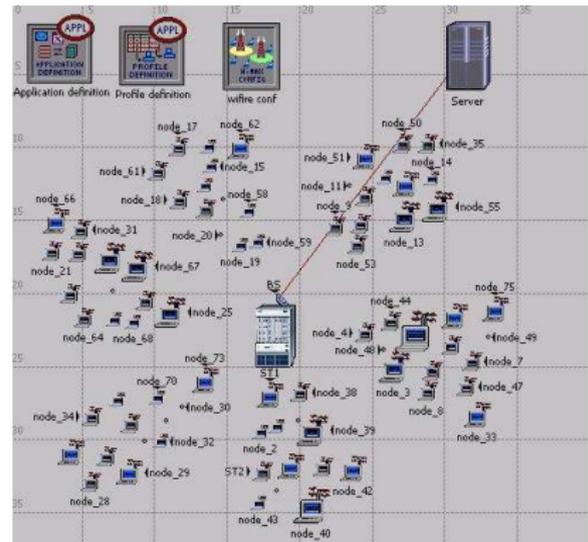

Figure: Scenario with 120 STs and unit distance of 5 Km

Performance plots for experiment to simulate VoIP calls

- ▶ Each ST requesting Bandwidth of 120Kbps
- ▶ Requested rate with MACoverhead is 130Kbps
- ▶ Load is 120Kbps, Actual traffic sent is 130Kbps

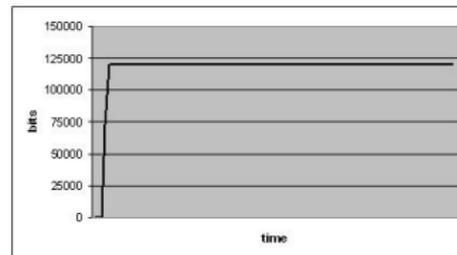

Figure: Load of the system

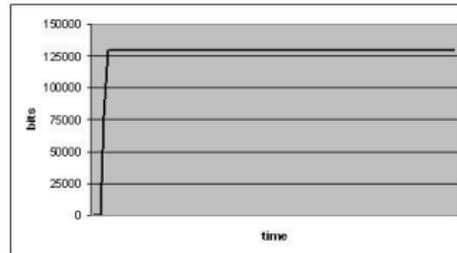

Figure: Actual traffic sent

Theoretical number of VoIP calls supported

Original Bandwidth request from ST = 120Kbps

$$\begin{aligned} \text{Requested rate with MACoverhead} &= rate \times \left(\frac{avg_pkt_size + WiFiRe_header}{avg_pkt_size} \right) \\ &= (120 \times 10^3) \times \left(\frac{60 + 5}{60} \right) = 130Kbps \end{aligned}$$

Requested rate in symbols per second =

$$\begin{aligned} rate_mac \times \left(\frac{1}{number_of_bits_persymbol \times coding_rate} \right) \\ = (130 \times 10^3) \times \left(\frac{1}{1 \times \frac{1}{2}} \right) = 260 \times 10^3 \end{aligned}$$

Number of symbols required per frame = (req rate in sps) × (frame duration)

$$\text{symbols per frame} = 260 \times 10^3 \times 10 \times 0.001 = 2600 \text{ symbols}$$

$$\text{symbols per slot} = \frac{32}{0.045} = 711 \text{ symbols}$$

WiFiRe PHY overhead = 96 micro sec

Number of symbols with WiFiRe PHY overhead =

$$\frac{\text{PHY_overhead_duration}}{\text{Symbol_duration}} = 2133 \text{ symbols.}$$

Total number of symbols required is sum of PHY overhead and requested rate

$$= \text{PHY overhead} + \text{Number of symbols requested}$$

$$= 2133 + 2600 = 4733 \text{ symbols}$$

$$\text{Total number of slots} = \frac{\text{Total_number_of_slots}}{\text{symbols_for_slot}}$$

$$= \frac{4733}{711} = 6$$

$$\text{Down link bandwidth} = \frac{66}{100} \times 11 * 10^6 = 7.26 \times 10^6$$

With 40 ST's ratio each ST has 323 Kbps if voice packet server in two frames

$$= \frac{7260 \text{ Kbps}}{40} \times 2 = 323 \text{ Kbps}$$

similarly with 120 STs it is around 119 Kbps which is close to requested bandwidth

Traffic received and Throughput for 40 STs

- ▶ All STs got Bandwidth allotted with theoretical calculation of 66 percentage DL Bandwidth
- ▶ Throughput is equal to traffic sent
- ▶ Each ST has 3 data slots and 3 phy slots
- ▶ Three VoIP calls are supported by each ST

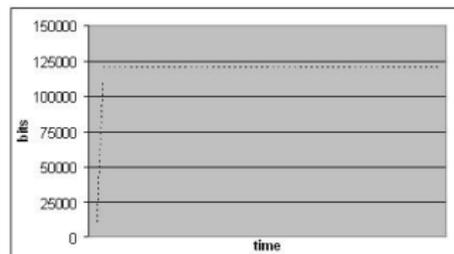

Figure: Traffic received for 40 STs

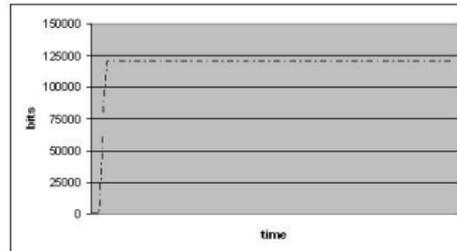

Figure: Throughput for 40 STs

Queuing delay and datadropped for 40 STs

- ▶ Arrival rate is equal to service rate
- ▶ Queuing delay is constant
- ▶ No traffic dropped

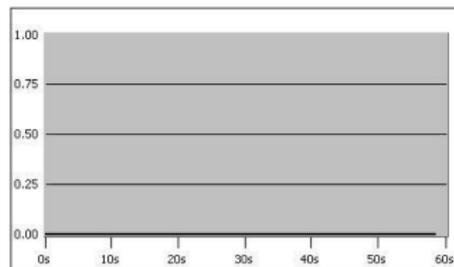

Figure: Data drop for 40 STs

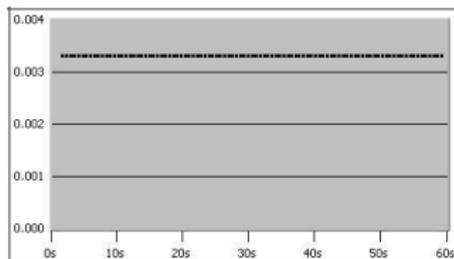

Figure: Queuing delay for 40 STs

Data dropped and queuing delay for 120 STs

- ▶ No sufficient bandwidth allotted to STs
- ▶ Queuing delay varies
- ▶ Queue will be filled packets are dropped

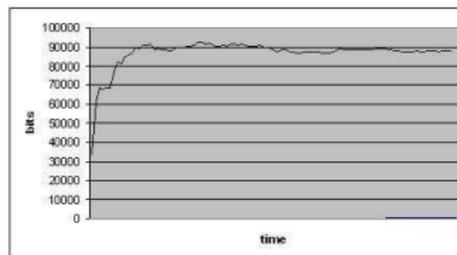

Figure: Data drop for 120 STs

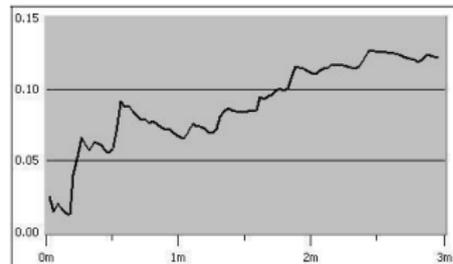

Figure: Queuing delay for 120 STs

Throughput for 120 STs

- ▶ Bandwidth not sufficient for STs
- ▶ Throughput is less compared to traffic sent

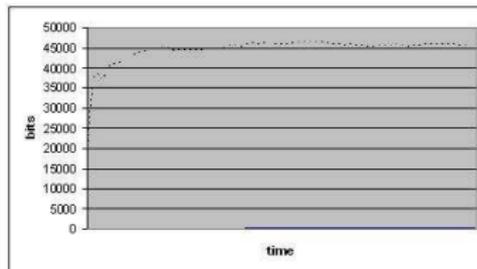

Figure: Throughput for 120 STs

Experiment to simulate VoIP and Video scenario

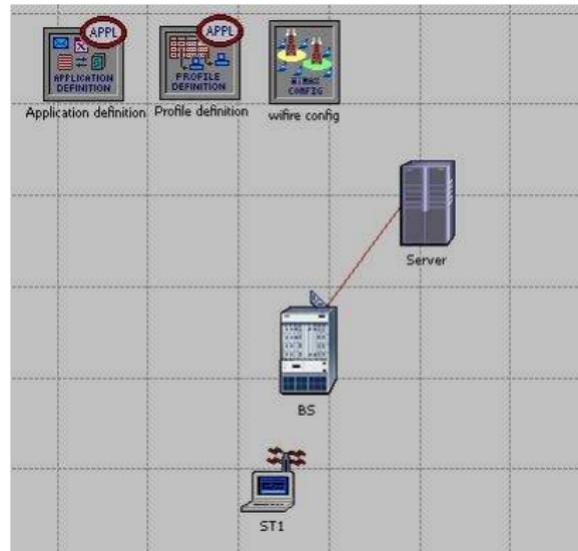

Figure: Scenario with ST and unit distance of 5Km

End to End delay for UGS

- ▶ This experiment is based on earlier model to simulate VoIP and Video Scenario by changing parameters
- ▶ The type of scheduling used is round robin
 - ▶ BS first allocates admitted number of slots for UGS flows.
 - ▶ Allocates requested number of slots for rtPS, if the requested number of slots are less than the admitted number of slots.
- ▶ UGS requesting 120Kbps serving smoothly
- ▶ BS allocates requested no of slots to UGS

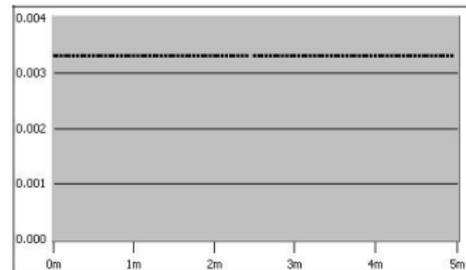

Figure: End to end delay for UGS

End to End delay for rtPS

- ▶ rtPS connection requesting 120Kbps
- ▶ End to end delay is initially high, as BS allocates admitted slots to UGS
- ▶ End to end delay gradually reduces to constant after getting requested number of slots

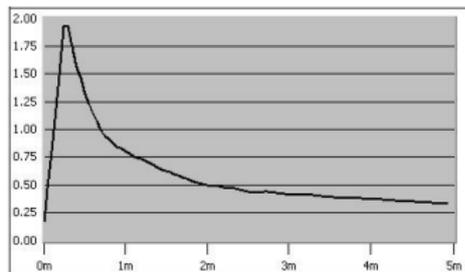

Figure: End to end delay for rtPS

Throughput for UGS and rtPS

- ▶ Throughput of UGS connection is high initially compared to rtPS
- ▶ As BS first allocates admitted number of slots to UGS
- ▶ Throughput of rtPS reaches 120Kbps after some time with requested rate

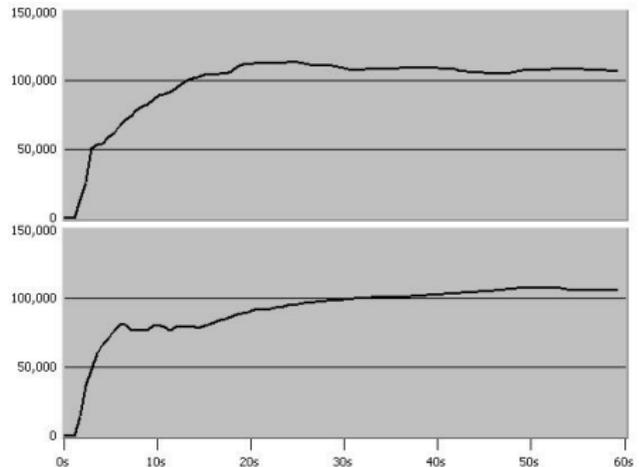

Figure: Throughput of UGS and rtPS

Conclusion

- ▶ Implemented WiFiRe model in OPNET
- ▶ Directional Antennas are modelled
- ▶ Pipeline stages are implemented to simulate physical behaviour of wireless link
- ▶ Results shows the model is working as expected

Future Work

- ▶ More experiments need to be performed in order to check performance of WiFiRe.
- ▶ The Performance questions are to be answered based upon different parameters are
 - ▶ What is the maximum number of users per sector and throughput in the sector which depends up on maximum throughput that channel can achieve
 - ▶ Number of packets dropped which depends on number of service flows and number of active users in the sector
 - ▶ Maximum number of allowed connections per ST

Thank You
